Sheen ...	9, 10, 11, 12	On Movable Kidney, Dr. Kendal Franks (Six Figures) ...	886, 897, 898
A Urethral Knife, Dr. J. MacMunn ...	18	A Hitherto Undescribed Locality in the Male Urinary Bladder where a Stone may Elude Contact with any Urethral Instrument, Mr. G. Buckston Browne ...	909
Celuloid Vaginal Douche, Mr. R. H. Rains ...	18	Breach Pin of Gun in Orbit, Dr. C. Wenyon ...	920
Improved Tonsil Guillotine, Mr. L. Roper ...	18	An Infirmary Ward, Cootehill Workhouse ...	920
Plan of a Part of the Blackburn Waterworks ...	22	Lunatics in the Airing Court, Cootehill Workhouse ...	924
Portrait of Professor Huxley ...	30	Portrait of Surgeon-General Sir T. Longmore ...	930
A Vaporiser ...	54	Sequel to a Case of Lateral Anastomosis by means of Murphy's Button, Mr. C. A. Morton ...	952
A Skin Grafting Knife, Mr. F. C. Wallis ...	54	A Series of Cases of Colectomy, Mr. A. W. M. Robson (Three Figures) ...	965
Coliotomy for Volvulus of the Sigmoid in a man aged 85, Mr. J. Greig Smith and Mr. C. E. S. Flemming (Three Figures) ...	122, 123, 124	A Simple Form of Exhaustion Pump for Use after Suprapubic Cystotomy, Mr. C. W. Cathcart ...	968
A Modification of the Operation of Pyloroplasty, Mr. A. W. Mayo Robson (Four Figures) ...	124	The Treatment of Resistant Talipes Equinus in Adults and Adolescents, Mr. E. M. Little (Six Figures) ...	979, 971
Gunshot Injuries produced by the Lee-Metford Rifle, Surgeon-Captain H. Knaggs (Two Figures) ...	131	Spontaneous Fracture of Uric Acid Calculi, Dr. C. B. Plowright (Three Figures) ...	972, 973
Dislocations of Carpus Backwards, Dr. T. H. Morton ...	132	Paupers and their Feeding Troughs ...	1056
A Curious Fracture of the Forearm, Surgeon-Captain H. G. Pridmore ...	132	The Pathology and Clinical History of Some Rare Forms of Bony Ankylosis, Mr. H. Marsh (seven Figures) ...	1067, 1068, 1069
An Operating Afro-Urethroscope, Mr. E. H. Fenwick ...	137	Naso-pharyngeal Snare, Mr. G. Stoker ...	1100
A Thermo-Anaesthetic Inhaler, Dr. R. W. Carter ...	137	A Case of Complete Laryngectomy, Dr. J. Solis Cohen ...	1100
Donaria of Medical Interest, Dr. L. Sambon (Fourteen Figures) ...	147, 148, 149, 217, 218	Dislocation of the Femur on to the Pubes, Mr. J. G. W. Flower (Two Illustrations) ...	1101
Ovarian Hernia and the Protrusion of the Appendages through Rupture of the Vaginal Wall, Dr. J. Ward Cousins ...	186	Pneumatic Tyres and Quiet Carriages ...	1111
Improved Artery Forceps, Dr. E. Mansel Simpson ...	197	Lattice Elastic Stocking and Legging ...	1111
Art in its Relation to Anatomy, Mr. W. Anderson (Thirteen Figures) ...	350, 351, 352, 353, 354, 355, 356	Tongue Depressor and Guard, Dr. A. W. Dowling ...	1158
The Arcuocelo ...	380	Dissection of Guinea Pig Showing Enlargement of Glands after Inoculation with Tuberculous Material, Dr. W. Milligan ...	1225
Diphtheria and its Treatment by Antitoxin, Dr. Sidney Martin (Two Figures) ...	463	The Treble Spring Truss, Dr. J. Ramage (Four Figures) ...	1242
Etiology of Nasal Polypi, Dr. Zuokerkandi (Two Figures) ...	477	Turbinotomy in Deafness and Tinnitus Aurium, Mr. T. Carmalt Jones (Two Figures) ...	1269
Underground Workshops, Drs. F. F. Waldo and D. Walsh ...	519	Aseptic Spongeholder, Dr. R. W. Felkin ...	1304
Portrait of Dr. J. S. Bristowe ...	563	A Paracentesis Needle for Use with Hypodermic Syringe, Dr. W. R. Huggard ...	1304
The "Watch Pocket Compactum" Instrument Case, Dr. S. H. Appleford ...	603	Some Superficial Affections of the Red Portions of the Lips, Dr. W. A. Jamieson (Two Figures and Coloured Plate) ...	1411, 1412
The Nervous Sequels of Infectious Disease, Dr. H. Handford (Five Figures) ...	704, 705, 706	The Red Light Treatment of Small-pox, Dr. N. R. Finsen ...	1414
A Case of Sciopody, Mr. D'Arcy Power ...	712	Cellulitis Treated with Marmorek's Antistreptococcal Serum, Dr. F. Heatherley (Two Figures) ...	1417
A New Urethrometer, Mr. C. J. Mayhew (Two Figures) ...	722	Multiple Enlargements of the (Long) Bones with Spontaneous Fractures, Mr. G. G. Sinclair (Two Figures) ...	1419
An Improved Intrauterine Catheter, Mr. J. Edgar ...	722	A Case of Cut Throat, Mr. W. T. Thomas (Three Figures) ...	1420
A New Bag for the Induction of Premature Labour, etc., Dr. J. Shaw ...	722	Thoracopagus Male Twins, Mr. C. M. Kempe ...	1421
New Vaccinator, Mr. J. Iredale (Two Figures) ...	730	Bill of Fish in Orbit, Surgeon-Major W. R. Thomson ...	1429
Bird's Eye View and Ground Plan of an Irish Workhouse ...	741	Dislocation of Carpus Backwards, Mr. J. Hossack ...	1434
An Adjustable Lock for Obstetric Forceps, Mr. E. McW. Bourke ...	763	Traumatic Aneurysm of the Anterior Temporal Artery, Mr. B. Robinson ...	1434
Infirmary Ward, Cootehill Workhouse ...	796	Hypodermic Syringe ...	1433
New Feeding Bottle (Two Figures) ...	843	Anti Stoop ...	1433
Portrait of M. Pasteur ...	872	Mechanical Road Carriages (Two Figures) ...	1434, 1435
The Diagnosis and Treatment of Fractures of the Upper Third of the Femur, Sir W. Stokes (Seventeen Figures) ...	881, 882, 883, 884, 885, 886, 887	The Treatment of Encysted Vesical Calculi, Mr. F. A. Southam ...	1490
The Diagnosis and Treatment of Fractures of the Upper Third of the Femur, Dr. E. H. Bennett (Thirteen Figures) ...	890, 891, 892, 893	Invalid Bed (Two Figures) ...	1503
		A Two-headed Monster, Dr. Griffiths (Two Figures) ...	1505, 1506

INDEX TO VOLUME II FOR 1895.

A.

Abbott, Mr. C. E., round shoulders, 1710
 Abcarius, Dr. J. J., a curious poultice, 685
 Abdomen, epistemic leucorrhoea following a blow on, 1106; the topographical anatomy of the, 1211; blood vessel in the, 1214
 Abortion, a rare form of, 1682; and child murder, 1243
 Abraham, Dr. P., the latency of leprosy, 1283
 Abram, Dr. J. H., A Handbook of Pathological Anatomy, rev., 1212; exophthalmic goitre, 1040; lamellar fibromata, 1493
 Abscess, abdominal, laparotomy, recovery, 779; anal, followed by portal pyemia and secondary abscesses of the liver, 971; of spleen, 1220
 Absorption, physical factors in, 1252
 Absorbent and non-absorbent travelling, 1147
 Académie de Médecine de Paris, prizes at, 1039
 Academy of Medicine, New York, list of Fellows of, 1210
 — Royal of Medicine in Ireland, list of officers, etc., of, 1126
 — Royal of Medicine in Ireland, Sections of Medicine and State Medicine, conjoint meeting of, 1213; the infectious hospitals (Dublin) scheme, 121; isolation of fever cases, 121
 — Royal of Medicine in Ireland, Section of Obstetrics, specialties, 1210; paper, 121
 — Royal of Medicine in Ireland, Section of Pathology, two central examinations, 1217; rupture of the heart, 1223; myoma of uterus, 121; tumours of the kidney composed of suprarenal tissue, 1218
 — Royal of Medicine in Ireland, Section of Surgery, colotomy, 1211; lumbar colotomy, 121
 Acetylene as an illuminant, 1210
 Acland, Sir H. W., presentation to, 1217; the "Index Medicus," 1210
 Actinomyces, with dental complications, 1210
 Act. Notification, payments under, 1217
 — Registration of births and deaths, conviction under, 99
 Acta, Public Health, difficulties in administration of, 1210
 — The Vaccination, suggestions as to amendment of, 1210, 1211; presentation under, 1210; difficulties under, 1210, 1211
 Adamkiewicz, Professor, elected corresponding member of the Paris Academy of Medicine, 1210
 Adams, Mr. P. D., new form of scleritis and inflammation, 1210
 Address, presidential at annual meeting by Sir J. Russell Reynolds, 211, 212, 213; in Medicine at the annual meeting by Sir W. Broadbent, 211, 212; in Surgery at the annual meeting by Mr. Jonathan Hutchinson, 211, 212, 213; at the opening of the Section of Medicine at the annual meeting by Dr. F. W. Pavy, 217; at the opening of the Section of Surgery at the annual meeting by Sir W. Mac Cormac, 211, 212; at the opening of the Section of Pathology and Bacteriology at the annual meeting by Sir W. G. Frazer, 211, 212; at the opening of the Section of Public Medicine at the annual meeting by Mr. Ernest Hart, 211; in Physiology at the annual meeting by Professor E. A. Schwarz, 211, 212, 213; at the opening of the Section of Pathology and Bacteriology at the annual meeting by Sir W. G. Frazer, 211, 212; at the opening of the Section of Physiology and Anatomy at the annual meeting by Sir F. Simon, 211; at the opening of the Section of Hygiene at the annual meeting by Sir W. F. Garrod, 211, 212; at the opening of the Section of Diseases of Children at the annual meeting by Mr. J. H. Morgan, 211; presidential in the Section of Pathology by

Dr. W. J. Mickle, 707; presidential in the Section of Otology at the annual meeting, 1219; presidential in the Section of Physiology at the annual meeting by Dr. D. Ferrier, 1277; presidential in the Section of Pathology at the annual meeting by Dr. S. Wilks, 1201
 Adenoid vegetations, 1218
 Adenoma of sebaceous glands, 1225; sebaceous, intermingled with flaccid mollusca fibrosa, treatment by excision, 1225
 Adolescence, the inebriety of, 1270
 Advertisements, public, of vacancies, local candidates and, 119; paragraph, 1209; immoral, 1209
 Advertising, professional, 1210, 1211, 1212, 1213, 1214, 1215, 1216, 1217, 1218, 1219, 1220, 1221, 1222, 1223, 1224, 1225, 1226, 1227, 1228, 1229, 1230, 1231, 1232, 1233, 1234, 1235, 1236, 1237, 1238, 1239, 1240, 1241, 1242, 1243, 1244, 1245, 1246, 1247, 1248, 1249, 1250, 1251, 1252, 1253, 1254, 1255, 1256, 1257, 1258, 1259, 1260, 1261, 1262, 1263, 1264, 1265, 1266, 1267, 1268, 1269, 1270, 1271, 1272, 1273, 1274, 1275, 1276, 1277, 1278, 1279, 1280, 1281, 1282, 1283, 1284, 1285, 1286, 1287, 1288, 1289, 1290, 1291, 1292, 1293, 1294, 1295, 1296, 1297, 1298, 1299, 1300, 1301, 1302, 1303, 1304, 1305, 1306, 1307, 1308, 1309, 1310, 1311, 1312, 1313, 1314, 1315, 1316, 1317, 1318, 1319, 1320, 1321, 1322, 1323, 1324, 1325, 1326, 1327, 1328, 1329, 1330, 1331, 1332, 1333, 1334, 1335, 1336, 1337, 1338, 1339, 1340, 1341, 1342, 1343, 1344, 1345, 1346, 1347, 1348, 1349, 1350, 1351, 1352, 1353, 1354, 1355, 1356, 1357, 1358, 1359, 1360, 1361, 1362, 1363, 1364, 1365, 1366, 1367, 1368, 1369, 1370, 1371, 1372, 1373, 1374, 1375, 1376, 1377, 1378, 1379, 1380, 1381, 1382, 1383, 1384, 1385, 1386, 1387, 1388, 1389, 1390, 1391, 1392, 1393, 1394, 1395, 1396, 1397, 1398, 1399, 1400, 1401, 1402, 1403, 1404, 1405, 1406, 1407, 1408, 1409, 1410, 1411, 1412, 1413, 1414, 1415, 1416, 1417, 1418, 1419, 1420, 1421, 1422, 1423, 1424, 1425, 1426, 1427, 1428, 1429, 1430, 1431, 1432, 1433, 1434, 1435, 1436, 1437, 1438, 1439, 1440, 1441, 1442, 1443, 1444, 1445, 1446, 1447, 1448, 1449, 1450, 1451, 1452, 1453, 1454, 1455, 1456, 1457, 1458, 1459, 1460, 1461, 1462, 1463, 1464, 1465, 1466, 1467, 1468, 1469, 1470, 1471, 1472, 1473, 1474, 1475, 1476, 1477, 1478, 1479, 1480, 1481, 1482, 1483, 1484, 1485, 1486, 1487, 1488, 1489, 1490, 1491, 1492, 1493, 1494, 1495, 1496, 1497, 1498, 1499, 1500, 1501, 1502, 1503, 1504, 1505, 1506, 1507, 1508, 1509, 1510, 1511, 1512, 1513, 1514, 1515, 1516, 1517, 1518, 1519, 1520, 1521, 1522, 1523, 1524, 1525, 1526, 1527, 1528, 1529, 1530, 1531, 1532, 1533, 1534, 1535, 1536, 1537, 1538, 1539, 1540, 1541, 1542, 1543, 1544, 1545, 1546, 1547, 1548, 1549, 1550, 1551, 1552, 1553, 1554, 1555, 1556, 1557, 1558, 1559, 1560, 1561, 1562, 1563, 1564, 1565, 1566, 1567, 1568, 1569, 1570, 1571, 1572, 1573, 1574, 1575, 1576, 1577, 1578, 1579, 1580, 1581, 1582, 1583, 1584, 1585, 1586, 1587, 1588, 1589, 1590, 1591, 1592, 1593, 1594, 1595, 1596, 1597, 1598, 1599, 1600, 1601, 1602, 1603, 1604, 1605, 1606, 1607, 1608, 1609, 1610, 1611, 1612, 1613, 1614, 1615, 1616, 1617, 1618, 1619, 1620, 1621, 1622, 1623, 1624, 1625, 1626, 1627, 1628, 1629, 1630, 1631, 1632, 1633, 1634, 1635, 1636, 1637, 1638, 1639, 1640, 1641, 1642, 1643, 1644, 1645, 1646, 1647, 1648, 1649, 1650, 1651, 1652, 1653, 1654, 1655, 1656, 1657, 1658, 1659, 1660, 1661, 1662, 1663, 1664, 1665, 1666, 1667, 1668, 1669, 1670, 1671, 1672, 1673, 1674, 1675, 1676, 1677, 1678, 1679, 1680, 1681, 1682, 1683, 1684, 1685, 1686, 1687, 1688, 1689, 1690, 1691, 1692, 1693, 1694, 1695, 1696, 1697, 1698, 1699, 1700, 1701, 1702, 1703, 1704, 1705, 1706, 1707, 1708, 1709, 1710, 1711, 1712, 1713, 1714, 1715, 1716, 1717, 1718, 1719, 1720, 1721, 1722, 1723, 1724, 1725, 1726, 1727, 1728, 1729, 1730, 1731, 1732, 1733, 1734, 1735, 1736, 1737, 1738, 1739, 1740, 1741, 1742, 1743, 1744, 1745, 1746, 1747, 1748, 1749, 1750, 1751, 1752, 1753, 1754, 1755, 1756, 1757, 1758, 1759, 1760, 1761, 1762, 1763, 1764, 1765, 1766, 1767, 1768, 1769, 1770, 1771, 1772, 1773, 1774, 1775, 1776, 1777, 1778, 1779, 1780, 1781, 1782, 1783, 1784, 1785, 1786, 1787, 1788, 1789, 1790, 1791, 1792, 1793, 1794, 1795, 1796, 1797, 1798, 1799, 1800, 1801, 1802, 1803, 1804, 1805, 1806, 1807, 1808, 1809, 1810, 1811, 1812, 1813, 1814, 1815, 1816, 1817, 1818, 1819, 1820, 1821, 1822, 1823, 1824, 1825, 1826, 1827, 1828, 1829, 1830, 1831, 1832, 1833, 1834, 1835, 1836, 1837, 1838, 1839, 1840, 1841, 1842, 1843, 1844, 1845, 1846, 1847, 1848, 1849, 1850, 1851, 1852, 1853, 1854, 1855, 1856, 1857, 1858, 1859, 1860, 1861, 1862, 1863, 1864, 1865, 1866, 1867, 1868, 1869, 1870, 1871, 1872, 1873, 1874, 1875, 1876, 1877, 1878, 1879, 1880, 1881, 1882, 1883, 1884, 1885, 1886, 1887, 1888, 1889, 1890, 1891, 1892, 1893, 1894, 1895, 1896, 1897, 1898, 1899, 1900, 1901, 1902, 1903, 1904, 1905, 1906, 1907, 1908, 1909, 1910, 1911, 1912, 1913, 1914, 1915, 1916, 1917, 1918, 1919, 1920, 1921, 1922, 1923, 1924, 1925, 1926, 1927, 1928, 1929, 1930, 1931, 1932, 1933, 1934, 1935, 1936, 1937, 1938, 1939, 1940, 1941, 1942, 1943, 1944, 1945, 1946, 1947, 1948, 1949, 1950, 1951, 1952, 1953, 1954, 1955, 1956, 1957, 1958, 1959, 1960, 1961, 1962, 1963,  Yaws, in Yaguag, Grenada, St. Vincent, and the Leeward Islands (Report on, Dr. H. A. A. Nichols, rev., 701) and coko, 871
 Yellowlegs, Dr., the Harvarian oration, 21
 Yoo, Dr. I. B., on medicine and society, 1073
 Yeomanry, promotions and appointments in the medical staff of, 504, 608, 700, 1208
 Yonge, Dr. K. S., a case of chloride tubercula, 1008
 Young, Professor A. H., the development and structure of the placenta, 1

THE
WEEKLY EPITOME
OF
CURRENT MEDICAL LITERATURE,
BEING A
SUPPLEMENT
TO THE
British Medical Journal.

JULY TO DECEMBER.

London:

PRINTED AND PUBLISHED BY THE BRITISH MEDICAL ASSOCIATION, AT THEIR OFFICE, 69, ST. AND.

—
MDCCLXXV.

INDEX TO THE EPITOME FOR VOLUME II FOR 1893.

The Figures in this Index refer to the Number of the Paragraph NOT the Page.

- A.**
Abdomen, the physical signs of disease of, 147.
Abdominal section, by cow's horn, 358; for puerperal septicaemia, 427.
Abels, tetanus from tongue-bites in eclampsia of pregnancy, 425.
Abortion, artificial, 96; decidua vera intact, 125; tubal and operation, 235; difficulty of inducing in a case of hyperemesis gravidarum, 393; treatment of, 397.
Abscess, subpyloric, 4; pelvic communicating with intestine, 13; retropharyngeal, sudden death on opening, 194; tubo-ovarian, vomiting of emaciated after operation, 299; of the lung in influenza, 358; subdiaphragmatic following gastric ulcer, 418.
Absorption and excretion, 184.
Acardiac and the twin cords, 74.
Acromegaly, pituitary extract in, 457.
Acroparasthesia, 426.
Actinomycosis of internal organs and peritoneum, 113; a study of, 233; of ovary, 308; the treatment of, 319; primary pulmonary, 426.
Acland, the lungs of one of Koch's earliest tuberculin patients, 397.
Adductor spasm in osteomalacia, 43.
Adrena, fatal fat embolism after forcible straightening of both knee-joints, 407.
Aeron, tuberculosis of the submaxillary gland, 71.
Airel, 413.
Akerman, osteomyelitis produced by bacterium coli commune, 144.
Akerman, movable kidney, 344.
Akerman, argemine in gonorrhoea, 109.
Albion, foreign bodies in the uterus, 273.
Albumen in urine, a new method of estimating, 63.
Albuminuria, the prognosis of in typhoid, 169; without, 361.
Alcohol, direct applications of in phlegmonous inflammation, 18.
Alcoholism in children, 393; myocarditis in, 399.
Aligayer, subcutaneous injections in syphilis, 313.
Allopia, syphilitic, treatment of, 397; areata, treatment, 361.
All, vaccine injections in otitis media, 41.
Almon, eclampsia of pregnancy with, 174.
Amsterdam, serum treatment of diphtheria at the Children's Hospital at, 36.
Amygdophenol, 426.
Amyl nitrite in pneumonia, 470.
Anaemia, chronic transfusion in, 449.
Anaesthesia, local, the infiltration method of, 109.
Analgescin, the antithermic, 467.
Anesthetics, the action of, 396.
Angeles, the effect of trophing in choked disc, 349.
Anger, serum treatment of malignant disease, 15.
Angina pectoris, gouty arthritis, and diabetes, 87.
Anthony, diffuse hypertrophy of breasts after delivery, 399.
Anthrax, the infection of, 299.
Antipyretic, action of on the blood, 181.
Antipyrin, in diseases of children, 189; in tanic acid solution as a styptic, 429.
Antithrombin, the relation between coagulation and the action of, 395.
——— the cholera, 161.
——— diphtheria treatment by, 330, 497.
——— typhoid, 37, 392.
Aphasia, motor, 293.
Apostroph, 481, and atrophin, 428.
Aplea, paralytic dislocation of the hip, 365.
Argemine in gonorrhoea, 109.
Argonin, a new geraniol, 264; in gonorrhoea, 397.
Army, French, diphtheria in, 361.
Aseptic, parenchymatous injections of in cancer, 459.
Artery, spermatic and veins, effects of ligature upon the testes, 295.
Arthritis, gouty, angina pectoris, and diabetes, 87.
Asaetide in obstetrics, 349.
Aschaff, primary pulmonary actinomycosis, 426.
Ascoli, treatment of diabetes, 314.
Athetoid attitude in Friedreich's disease, 169.
Atrophy, crossed cerebello-cerebellar, 290; progressive muscular pathological anatomy of, 318; senile yellow, following twisted pedicle and ovariectomy, 465.
Auché, urinary toxicity in variola, 299.
Aufrecht, myocarditis in alcoholism, 459.
Ausset, calf's pancreas in pancreatic diabetes, 184.
Auto-intoxication and skin diseases, 360.
Autopsy of the larynx, 159.
Auvard, the protection of the internal organs in gonorrhoea, 194.
Axis, luxation of forward, 193.
B.
Bacillus, of diphtheria, and fibrinous rhinitis, 43; typhoid, intrauterine infection with the, 95, 358; of cholera in new milk, 104; of tubercle, examination of sputum for, 126; a pathogenic in broncho-pneumonia, 376; of diphtheria, cultivation of, 507.
Baciocchi, laparotomy in tuberculous peritonitis, 69.
Bacteria in the urine in typhoid fever, 417.
Bacterium coli commune, immunisation against the surgical lesions due to, 125; osteomyelitis produced by, 144.
Baldy, abdominal section for puerperal septicaemia, 427.
Ballet, aeroparasthesia, 426.
Ballowitz, solitary kidney, 338.
Banas, tuberculosis and neoplasm of bladder; surgery or hygiene? 214.
Banti, infective jaundice, 168; histological appearances of the heart muscle in valvular lesions, 297.
Baqis, conjunctivitis due to larvae, 441.
Bar, opels during pregnancy, 444; transmission of tuberculosis through the placenta, 455.
Bard, antipyretic effects of guaiacol externally applied, 426.
Bassau, the cholera bacillus in new milk, 104.
Bastian, the relation of sensory impressions and sensory centres to voluntary movements, 65.
Bastianelli, infection of the urinary tract, 354.
Bauer, subcutaneous emphysema after intubation, 399.
Baumel, flooding and laceration neonatorum, 367.
Bazy, urinary infection, 213.
Bechterew, experimental physiology of the nervous system, 278.
Benckin, uncontrollable vomiting of pregnancy, 429.
Berger, trional poisoning, 314; the operative treatment of simple fractures, 459.
Bergh, cysticercus cellulosa in man, 343.
Bergmann, v., recent advances in cerebral surgery, 91.
Beri, the microbe of scurvy, 243.
Berliner, treatment of itching in urticaria, 363.
Bertrand, treatment of snake bite by calcium chloride, 51.
Beumer, typhoid antitoxin, 37, 392; vaccine immunity, 461.
Bharbata of soda, direct influence of on the gastric secretion, 17.
Blaugheim, gastric peritonsitis, 145.
Boer, treatment of articular tuberculosis, 478.
Boisot, oral results of nasal applications, 394.
Boissac, pathogenesis of myopia, 426.
Boisier, tuberculosis and neoplasm of surgery of hygiene? 214; rupture of hamatocoele into in ectopic gestation, 299.
Boisier, auto-intoxication and skin diseases, 360.
Boissier, the pathology of, 426.
Boissier, the blood changes in gastric disorders, 422.
Bong, treatment of syphilitic alopecia, 397.
Bong, action of antipyrin on the 181.
Bong, changes in the in asphyxia, 442; modification of the coelomic cells of the blood vessels, 344; material, parastoma in, 424; changes in the in gastric disorders, 422.
Boisot, serum treatment of cancer, 257.
Boisot, incubation in diphtheria, 426.
Boisot, death in acute pneumonia, 168.
Borax in epilepsy, 394.
Bordoni-Uffreduzzi, internal localisation of the gonococcus, 299.
Bornmann, a case of pancreas administration, 451.
Boss, 133 cases of placenta previa, 311.
Boudant, trional as a hypnotic, 274.
Bourcart, cure of uterine disease by vibrations, 135.
Bovet, leguminous alimentation in diseases of digestion and nutrition, 129.
Bowel, Murphy's button in resection of, 465.
Bowen, camphorated calomel, 426.
Brain, the surgical treatment of medical intracranial lesions of, 29; recent advances in the surgery of the, 91; glioma of the left frontal lobe of, 107; compression of the, 363.
Braul, a new operation for varicocele, 461.
Braun, pregnancy in apparently imperforate hymen, 35.
Breast, primary tuberculosis of the, 49; the hysterical, 216.
Breasts, axillary, 155.
Breath, toxicity of the aqueous part of the, 379.
Breech presentation, rupture of child's perineum by midwife, 224.
Brenner, Murphy's button in resection of the bowel, 465.
Bresler, infantile progressive paralysis, 467.
Bressler, sulphonal, trional, and tetralol, 296.
Brisson, the thyroid body and Graves's disease, 297.
Broca, luxation of the axis forward, 193.
Broca, treatment of alveolar areata, 361.
Broca, involution of the uterus after labour, 116.
Bromhydrate of arecolin, 465.
Broncho-pneumonia, a pathogenic bacillus in, 373.
Brothers, spontaneous lamophilia in, 294.
Brow presentation, internal manipulation, 53.
Brunon, painful temporary paralysis in children, 68.
Bryson, castration for prostatic enlargement, 74; prostatectomy, 296.
Bulb, suppurating, iodoform ointment injections in, 177.
Bulbous, the treatment of, 166.
Buchner, immunity, 19.
Bureau, placental circulation and morphine-mania, 271.
Burnett, E. C., obstruction of ejaculatory ducts, 298.
Burns, death in, 166; ichthyol in the treatment of, 413.
Burns, enlarged about the knee, 299.
Bursar, secondary tuberculosis of the uterus involving the external os, 198.
Busquet, diphtheria in the French army, 361.
Button, Murphy's, in resection of the bowel, 465.
C.
Carcinoma, displaced, carcinoma of, 359.
Carcinoma, the health of workmen in, 24.
Calcium chloride, treatment of cystic bite by, 51.
Calculus in the Fallopian tube, 177.
Calais after fracture, amputation of the hip for tumour in, 497.
Cabot, the operative treatment of spinal caries, 94.
Campbell, treatment of inoperative malignant tumours by injection of crystalline toxins, 391.
Campbell, subcutaneous injections of, 459.
Canal, genital, normal range of growth in, 392.
Cancer, serum treatment of, 160, 257, 399, 400; valve vaginal leucorrhoea and, 118; of the stomach, carcinoma in, 274; of the stomach, surgical treatment of, 292; radical hysterectomy for, 417; parenchymatous injections of arecolin in, 459.
Capella, suprarenal, a toxic substance extracted from the, 411.

Germes, normal range of in the genital canal, 289.
Gestation, extrauterine, diagnosed at six months, operated on near term, 135; alleged ovarian, 251; ectopic, rupture of hematocoele into bladder, 29; ectopic, morphia infection, 280; ectopic, the uterus in, 145.
Geyl, edema and prolapse of cervix in labour and pregnancy, 45.
Gibson, compression of the brain, 369.
Gibson, urinary cirrhosis in children, 65.
Gomes de la Tourette, castration for hysteria, 73; the hysterical breast, 336.
Grandiden, hysteria and heart disease, 190.
Graded, submaxillary tuberculosis of, 71.
Gross, edema of left frontal lobe, 107.
Grosser, etiology of multiple tropical neuritis, 261.
Glycosuria, pharbitazine and, 143.
Guth, intravenous subcutaneous injections, 39.
Guthrie, encephalitis, pregnancy and, 114; administration of thyroxine in, 260; encephalitis, progress of, 43; thyroid treatment in, 439; encephalitis, persistent thymus in, 49.
Goldberg, gonorrheal cystitis cured by indurina, 83.
Goldberger, axillary breasts, 154.
Gonorrhea, internal localization of, 269.
Gonorrhea, uterine, 18; argentamine in, 100; the protection of the internal organs in, 134; in the newborn child, 281; argosin in, 236.
Gossman, hepatitis of pregnancy, 77.
Guttschalk, abortion, decidua vera intact, 120.
Guttschalk, Madame, new type of crossed hemiplegia, 240.
Goursier, a toxic substance extracted from the suprarenal capsule, 471.
Gout, the pathology and treatment of, 389.
Graeber, quinine as a prophylactic against influenza, 461.
Graham, displacements of the liver, 65.
Grandement, puerperal as a sudorifer, 40.
Graves' disease, 300.
Greene, a new method of treatment for vomiting, 263.
Griffiths, effects upon the testes of ligature of the spermatic artery and veins, 305.
Griffin, uterus bicornis in an aged multipara, 288.
Gross, the relation between coagulation and the action of antitoxin, 338.
Grossman, as a local anesthetic, 199; antipyretic effects of locally applied, 199; external application of in orchitis, 73; external use of, 501.
Gynecology, dangers of amateur massage in, 347.
Gynecomastia, so-called, 65.
H.
Hematocoeles, double vagina, single uterus, 14; lateral, 216.
Hematoma, large pelvic, after ovariotomy, 269.
Hematocoeles following amputation of cervix, 269.
Hemoglobinuria, paroxysmal, 67; quinine, 235.
Hemiplegia, spontaneous in brothers, 264.
Hemorrhage, intestinal, after herniotomy, 139.
Hagenbach-Schwarz, etiology of rickets, 1.
Hahn, epinephrine for splenic hydatid, 111.
Hamburger, absorption and excretion, 186.
Harris, epinephrine in 1899, 113.
Hartmann, the maternal impression theory, 263.
Hartung, leucocytosis in cancer of the stomach, 324.
Haskovec, tuberculosis of the spinal cord, 261.
Havas, lactation and syphilis, 269.
Hayden, the treatment of buboes, 186; iodoforn ointment in infections in suppurating bubo, 477.
Hayes, distention of stomach simulating heart disease, 199; stomach diseases, 215; objective signs in gastric disease, 209; treatment of chlorosis, 209; amyloid nitrite in pneumonia, 410.
Heart, distention of stomach simulating disease of, 199; hysteria and disease of, 199; histological appearances of the muscle of in valvular lesions, 267; hypertrophy of and normal growth, 269; puberty and disturbed action of the, 268.
Hecht, fetal tumour impeding labour, 156.
Heimreich, congenital sacral tumour impeding labour, 443.
Hofmann, persistent thymus in exophthalmic goitre, 40.
Holler, health of workmen in calissons, 247.
Humpage, crossed, new type of, 269.
Homocoele, action of antipyrine on the blood, 181.
Hof, treatment of soft cornea in females, 67.
Hornburt, carbon treatment of cancer, 269.
Hornburt, radical cure of, 26, 400; after ovariotomy, 183.
Herniotomy, intestinal hemorrhage after, 139.

Hertzsch, uterus didelphys, abortion, uterus bicornis with pyometra, 187.
Herzen, tryptic digestion and the internal secretion of the spleen, 265.
Heubner, the serum treatment of diphtheria, 491.
Hildebrandt, polyuria and citrophen, 466.
Hip, the operative treatment of congenital dislocation of the, 27; paralytic dislocation of the, 26; amputation at for tumour on callus after fracture, 467.
Hirschfeld, diabetic coma, 147.
Hitzig, abscess of the lung in influenza, 230.
Hlava, the action of vaccinia serum, 233.
Hook, defective development of sternum in a child aged 3 months, 266.
Hodara, treatment of chronic urethritis, 345.
Hoda, the operative treatment of congenital dislocation of the hip, 27.
Hofmehl, puncture in pyosalpinx and hydrosalpinx, 34.
Holst, the presence of streptococci and mastitis in cows as a cause of acute gastroenteritis in man, 268.
Honi, the action of vaccinia serum, 233.
Huchard, Stokes-Adams' disease, 433.
Hunklenbroich, induction of premature labour, 381.
Hut, parenchymatous injections of arsenic in cancer, 439.
Humerus, fracture of at birth, temporary paralysis, 58.
Humiston, tubo ovarian abscess, vomiting of emetata after operation, 269.
Hunter, the action of toluylenediamin and the pathology of jaundice, 269.
Hutcheon, the movements of the fontanelle, 264.
Hydatid, abdominal, the intraperitoneal treatment of, 464.
Hydrorrhea nasal, 321.
Hydrosalpinx, puncture in, 34.
Hymen, apparently imperforate, pregnancy in, 25.
Hymenodictyon, 314.
Hyperemesis, gravidarum, difficulty in inducing abortion, 261; due to local causes, 339.
Hypoplasia, treatment of, 179.
Hysterectomy, vaginal, hemostasis in, 28; removal of the inflamed appendages of, 156; vaginal for salpingitis, 187; vaginal on a large scale, 267; "collarette" operation in, 261; radical, for cancer, 410; total abdominal, 469.
Hystero myomectomy, 12.
Hysteria, castration for, 73; and heart disease, 190.
I.
Ice, contaminated and cholera, 42.
Ichthyol, in the treatment of phthisis, 141; in the treatment of burns, 463.
Idiocy, neonatorum, flooding and, 367.
Immunity, 19.
Infancy, laparotomy for acute suppurative peritonitis in, 139.
Infants, perimetritis from vulvitis in, 217.
Infiltration method of local anesthetics, 182.
Inflammation, phlegmonous, alcoholic applications in, 18.
Influenza, vascular obstruction in, 60; gonorrheal cystitis cured by, 90; abscess of the lung in, 230; and the female reproductive organs, 469; quinine as a prophylactic against, 461.
Insomnia in surgery and its treatment, 40.
Intubation, subcutaneous emphysema after, 26; in diphtheria, 474.
Iodoform, injections of in joint disease, 28.
Iodoform ointment, injections of in suppurating bubo, 477.
Iron as food and drug, 464.
Ipsen, division of the vas deferens for prostatic hypertrophy, 150, 263.
Israel, syphilitic endocarditis and myocarditis, 263.
Itching, treatment of in urticaria, 268.
J.
Jacob, treatment of abortion, 267.
Jadassohn, argosin in gonorrhea, 264.
Jannison, treatment of pediculosis scab. mentum, 264.
Jaundice, infective, 186; after lactophenin, 269; the pathology of and the action of toluylenediamin, 269; fatal in pregnancy, 411.
Jochim, epithelial, trinal, and internal, 269.
Joints, indurated infections in disease of, 26.
Johansen, urinary toxicity in uricemia, 219.
Jochert, menstruation in hot countries, 269.
Jouin, steroids cured by extract of thyroid gland, 263.
Justus, changes in the blood in syphilis, 242.

K.
Kahn, twin labour, placenta previa contralis, 265.
Kamppe, spontaneous straightening of rickety curvatures of the leg, 264.
Kapell, pemphigus, 262.
Karatell with hypopyon, a new treatment of, 423.
Keratocystoma in an infant the subject of congenital hemorrhagic syphilis, 411.
Kidney, calcareous, 264; movable, 264; congenital cysts, 266.
Kirstein, autotomy of the larynx, 139.
Kisch, puberty and disturbed heart's action, 266.
Klempner, goat, 269.
Knee, enlarged bursa about the, 269.
Knee-joints, fatal fat embolism after for the straightening of, 467.
Kneipenmacher, thyroid feeding, 211.
Kobak, gonorrhea in the newborn child, 281.
Koeppel, cerebral diplegia of children, 186.
Kopstein, the action of erysipelas serum on malignant growths, 261.
Kovalev, children and pregnancy, 461.
Kowa, the treatment of wandering spleen by splenectomy, 465.
Kraft-Ebing, association of migraine with neuritis, 419.
Krahl, ovariectomy in a patient over 64, 269.
Krause, intracranial resection of the trigeminal, 266.
Krisowski, hereditary syphilis, 266.
Kulz, the gases in women's milk, 60.
Kummel, removal of cancerous ovary and uterus with resection of bladder and intestines, 114; castration for prostatic hypertrophy, 189.
Kummer, radical cure of hernia, 464.
L.
Labour, involution of the uterus after, 114; fetal tumour impeding, 156; premature induction of, 261; missed, 261; rapid dilatation of the os during, 462; congenital sacral tumour impeding, 463.
Lactation, statistics of, 199; and syphilis, 269.
Lactophenin, jaundice after, 269.
Lafon, the reaction of sulpham in the urine.
Lagrange, atrophic atrophy in Friedrich's disease, 189.
Lampe, subphrenic abscess, 6.
Landau, vaginal hysterectomy on a large scale, 307.
Landoury, the diagnosis of diphtheria, 266.
Lannelongue, apparent double penis, 171; the plurality of osesymptoma, 469.
Lantana, the Brazilian, and its alkaloid, 277.
Laparotomy, in tuberculous peritonitis, 60; for acute suppurative peritonitis in infancy, 139.
Larra y Cerena, external use of guaiacol, 264.
Larsen, alleged ovarian gestation, 261.
Larsen, diphtheria, 469.
Larsen, conjunctivitis due to, 461.
Larynx, autotomy of the, 139.
La Torre, hyperemesis due to local causes, 269.
Lautent, treatment of hypoplasia, 179.
Le Conte, ruptured perineum, restoration of sphincter, 26.
Lecoe, the prognosis of albuminuria in typhoid, 189.
Leg, hematoma of the and emboli, 186; spontaneous straightening of rickety curvatures of the, 264.
Leguminous alimentation in diseases of digestion and nutrition, 129.
Leichtenstern, the serum treatment of diphtheria, 491.
Leistikow, ichthyol in the treatment of burns, 463; treatment of alopecia areata, 261.
Lembke, edema and atrophy of ovary from torsion, 263.
Leredda, acute tuberculosis of the bronchopneumonic form, 2.
Lente, subcutaneous injection of fat, 469.
Leucocytosis, the influence of on infectious diseases, 189; in cancer of the stomach, 189.
Leucoplakia, vulvo vaginal, and cancer, 119.
Louden, puerperal convulsions, 269.
Levi, wounds of vulva from taking acetate 26; percussion of the skull in encephalic lesions, 269.
Lavings, castration for prostatic enlargement, 269.
Lavy, intracranial infection with the typhoid bacillus, 26, 269.
Lacy-John, polymycosis with neuritis, 211.
Lewis, the use of vinegar for the arrest of vomiting after the administration of calomel, 112.
Lewis, induration method of local anesthesia, 189.

Lighting, death by, 185.
Lion, the physical signs of abdominal disease, 187; stomach diseases, 219; objective signs in gastric disease, 227.
Lithium salts, diuretic action of the, 323.
Lithotomy, suprapubic, in pregnancy, 436.
Litho, additional spasm in osteomalacia, 45.
Liver, displacement of the, 47.
Liverside, tenacity of the aqueous part of the breath, 279.
Loomerolary, the influence of syphilis on, 5.
Lowry, the influence of fever and leucocytosis on the course of infectious diseases, 183.
Lodge, atheistic attitude in Friedrich's disease, 186.
Loving, fracture of humerus at birth, temporary paralysis, 91.
Lowe-Championnière, glycerol as a local anesthetic, 132; parasthesia of the external cutaneous nerve of the thigh, 24.
Luz-Vila, the Brazilian lantern and the alcohol, 27.
Lui, treatment of epilepsy, 364.
Lutano, changes in nerve cells in different functional states, 296.
Lung, access of the in tuberculosis, No. 1, surgery of the, 431, 439.
Lungs, the, of one of Koch's earliest tubercle in patients, 261.
M.
McIlroney, saline infusion in cases of suppression of urine after surgical operation, 173.
McIlroy, treatment of obstruction of the common bile duct, 294.
McKenrick, oral results of ventrofixation of the uterus, 184.
McNair, morphology of Mastomys, 409.
Mergalio, oxyanide of mercury as an antiseptic, 365.
Meyer, health of workmen in calsones, 347.
Malesch, an epidemic of malignant pneumonia (pneumonia), 292.
Mann, the presence of streptococci and mastitis in cows as a cause of acute gastro-enteritis in, 261; cystitis, cellulitis in, 148.
Mann, a curious gastric condition, 299.
Mantoli, surgical treatment of meningitis, 247.
Marchand, vesicular mole followed by malignant changes, 166.
Marry, radical cure of hernia, 485.
Marlot, ferritin, 42.
Marx, calcium, diabetes with bronzing of the skin, 45; thyroid treatment in goitre, 422.
Marinoco, pituitary extract in acromegaly, 461.
Marquett, modifications of the colourless blood cells inside the blood vessels, 214.
Marr, pericarditis communicating with intestine, 13; pericarditis from vulvitis in infants, 217.
Marsage, amateur, danger of in gynecology, 347.
Mastitis in cows as a cause of acute gastro-enteritis in man, 261.
Maternal impression theory, the, 263.
Matheux, treatment of dilatation of the stomach, 59.
Maugue, Raynaud's disease in children, 399.
Meder, eryngomyoma, 67.
Meliard, spontaneous rupture of non gravid uterus, 14; the value of gastro-diagnosis, 40.
Menard, juxta-articular osseous tuberculosis, 226.
Mendelsohn, uric acid and its solvents, 189; diuretic action of the lithium salts, 223.
Meningitis, epidemic cerebro-spinal, diagnosis of, 17; surgical treatment of, 20; epidemic cerebro-spinal, 20; eryngomyoma, 67.
Menstruation and ovulation independent, 297; in hot countries, 119.
Mercuric chloride, intravenous injections of in syphilis, 161.
Mermann, excision in protracted cross-birth, 261.
Metchnikoff, the epidemiological conditions of cholera, 124.
Meyer, argemum, a new germicide, 224.
Microbe of curvy, the, 243.
Midwifery, digital exploration in, 441.
Migraine, association of with puerperia, 419.
Miles, skin grafting from the lower animals, 429.
Milk, infectiousness of, 45; women's, the gases in, 99; new, the chloera bacillus in, 187; woman's, each in, 272.
Milklin, a novel application of tendon grafting, 42.
Minguzzi, crossed cerebro-cerebellar atrophy, 20.
Mirabelli, laparotomy for acute suppurative peritonitis in infancy, 112.

Mirabelli, gastropathia xiphoides, 3; microtic origin of cisterns, 164.
Mister, excision of oesophageal pouch, 131.
Mole, vesicular, followed by malignant changes, 166; hydatidiform and malignant deciduoma, 261.
Monro, trional as a hypnotic, 274.
Money, the surgical treatment of medical intra-cranial lesions, 20.
Monet, vulvo-vaginal leukoplakia and cancer, 119; oxyanide of mercury as an antiseptic, 365.
Monster, double, dystrophia from, 263.
Morse, alcoholism in children, 393.
Morphine, injections in ectopic gestation, 260.
Morphomacina, placental circulation and, 271.
Morsinet, bromhydrate of areonin, 488.
Moser, the disinfecting power of the organic sulphonates, 267; influenza and the female generative organs, 409; eryngomyoma, 67.
Muret, double vagina, hematomatous, single uterus, 14; lateral hematomatous, 274.
Murphy's button. See button.
Mustard as an antiseptic, 470.
Mutach, congenital cystic kidney, 266.
Myallia, acute special, 64.
Myocarditis, epidemic, 263; in alcoholism, 490.
Myoma, treatment of by operation, 117; of the uterus, 409.
Myopia, pathogenesis of, 406.
Myxoma, contagious, 261.

N.
Nackell-Akerblom, treatment of pneumonia by digitalis, 162.
Nannotti, laparotomy in tuberculous peritonitis, 99.
Nasal. See Nose.
Nauwerck, influenza encephalitis, 168.
Navel, antiseptic treatment of in the newly born, 65.
Nephritis of pregnancy, 77.
Nephrosy, 115.
Nerve stretching, the treatment of perforating ulcer by, 363.
Nerve, ulnar, dislocation of at elbow, 62.
Nerve cells, changes in in different functional states, 299.
Nervous system, experimental physiology of the, 278.
Neumann, syphilis of vagina, uterus, and appendages, 42; subacute suppurative polyneuritis, 10; predisposing causes in facial paralysis, 379; slow pulse in childhood, 424.
Neuralgia, trigeminal, Rose's, operation for, 133.
Neuritis, polymyositis with, 211; multiple tropical, etiology of, 261.
Neuroses, association of with migraine, 419.
Neurotubes, peripheral, 26.
Nitrates, use of in infective diseases, 416.
Nocard, sterility of serum, 22; the serum therapeutics of tetanus, 413.
Nogues, dilatation of the vagina by the tampon ("columinisation"), 33.
Nola, the action of anemoin, 264.
Noorden v., early diagnosis of diabetes, 66.
Nose, evil results of applications to, 364.
Nothke, the thyroid body and Graves's disease, 267.
Nutrition, leguminous alimentation in diseases of, 123.

O.
Obel, glioma of left frontal lobe, 167.
Obstetric, anal-epitheloma in, 207.
Oedema without albuminuria, 261.
Onions, effect of on diuresis and perspiration in healthy persons, 261.
Oophorectomy, disappearance of tuberculosis of the peritoneum after, 224.
Oppenheim, aplastic cerebral diplegia, 245.
Orchitis, external applications of gualcol in, 274.
Organotherapeutics, 161.
Os, rapid dilatation of the during labour, 442.
Osteoarthritis, pulmonary hypertrophy, 266.
Osteomalacia, additional spasm in, 45.
Osteomyelitis, produced by bacterium coli communis, 144; the plurality of, 488.
Oils, examination of the chest, 25; treatment of advanced cases of phthisis, 223.
Olive media, vaccine injections in, 41.
Ovariotomy, as a source of fluid, recovery, 11; hernia after, 118; in a patient over 64, 389; large pelvic, hematomata after, 369; in a child aged 6, 402.
Ovary, cancerous, removal of, 114; oedema and apoplexy of from torsion, 26; actinomycosis of, 26.
Ovulation and menstruation independent, 262.
Oxyanide of mercury as an antiseptic, 365.

P.
Paealer, carcinoma of displaced caecum, 256.
Pancreas, treatment of cyst of the, 8; calc's in pancreatic diabetes, 184; administration of, 487.
Paralyses, painful temporary in children, 42.
Paralysis, facial, predisposing causes in, 279; infantile progressive, 492.
Parasites in variola, 454.
Park, antipyrin in tannic acid solution as a styptic, 488; mustard as an antiseptic, 470.
Parlavestino, suture of the vas deferens, 365.
Pavona, excision of the vas deferens for prostatic hypertrophy, 7.
Peon, lung surgery, 438.
Pediculosis vestimentorum, treatment of, 264.
Pelper, typhoid antitoxin, 37, 389; vaccine immunity, 401.
Pelvis, the, in lame female children, 10; the female, in primitive races, 426.
Pempingus, discussion on at the German Dermatological Congress, 219.
Penna, apparent double, 171.
Pericarditis, uranic, 24.
Pericarditis from vulvitis in infants, 217.
Perineum, ruptured, restoration of sphincter, 79; child's, rupture of in breech presentation, 264.
Peristalsis, gastric, 145.
Peritonium, disappearance of tuberculosis of after oophorectomy, 224.
Peritonitis, tuberculous, laparotomy in, 99; acute suppurative in infancy, laparotomy for, 112.
Perspiration, effect of onions on in healthy persons, 264.
Petron, use of nitrates, in infective diseases, 416.
Phenyl-hydrazin test for sugar in the urine, the clinical value of, 22.
Phisallix, treatment of snake bite by calcium chloride, 41.
Phlorhizine and glycosuria, 143.
Phurina, ichthyol in the treatment of, 141; treatment of advanced cases of, 223.
Piatot, sudden death on opening a retro-pharyngeal abscess, 194.
Piering, chloro-cannula, 61.
Piering, tubal abortion and operation, 237.
Pillet, the uterus in ectopic gestation, 445.
Pilocarpin as a sudorific, 49; in influenza pneumonia, 264.
Pineard, extrauterine gestation diagnosed at 6 months operated on near term, 175.
Pineus, hematomata and myositis of the sternomastoid muscle in newborn children, 346.
Pituitary extract in acromegaly, 447.
Placenta, previa centralis, with twin labour, 235; circulation in and morphinomania, 271; previa, 133 cases of, 311; transmission of tuberculosis through the, 455; previa, treatment of, 498.
Pleurisy, gonorrhoeal, 474.
Plexus, brachial, root paralysis of the, 228.
Plique, hematomata of the leg and emboli, 145.
Plicker, the surgical treatment of movable spleen, 362.
Pneumonia, treatment of by digitalis, 162; acute, death in, 165; malignant (pneumococci) an epidemic of, 262; amy nitrate in, 476; in influenza, pilocarpin in, 264.
Podack, diphtheria bacillus and fibrinous rhinitis, 44.
Podras, gastric ulcer treated by scraping and dilating the pylorus, 50.
Poison, the conditions regulating the production of in diphtheritic cultivations, 488.
Poisoning by cyanide, 24; by trional, 274.
Polisambic, epiglottitis without aphonia, 51.
Polymyositis with neuritis, 261.
Polyomyelitis, subacute suppurative, 9.
Potain, cardiac hypertrophy and normal growth, 322.
Potter, oedema and apoplexy of ovary from torsion, 265.
Pouch, oesophageal, excision of, 131.
Poulet, pilocarpin in influenza pneumonia, 264.
Poulsson, hydrophoria nasi, 321.
Pozzi, hematomatous following amputation of cervix, 260.
Pregnancy, nephritis of, 77; and exophthalmic goitre, 116; amaurosis with eclampsia of, 174; tetany in, 218; fatal jaundice in, 411; suprapubic lithotomy in, 426; uncontrollable vomiting of, 429; sepsis during, 444; ruptured interstitial, 446; cholera, 446; and, 481.
Prevost, motor aphasia, 262.
Pribram, prognosis of exophthalmic goitre, 487.
Prochownik, ectopic gestation, morphine injections, 260.
Prospero, treatment of tapeworm, 428.
Prostate, excision of the vas deferens for hyper-

Tenue perforation of uterus by a degenerated foetus, 432
 Test, urinary, infection of, 324
 Transfusion in chronic anemia, 417
 Transfusions, simple, and serum-evolutions, a test for distinguishing between, 1-2
 Trepanning in scyphoma, 327; the effect of in cracked disc, 343
 Tuberculous intracranial resection of, 364
 Trional in internal diseases, 371; as a hypnotic and sedative in internal diseases, 367; sublingual and internal, 369; as a hypnotic, 376; poisoning by, 374
 Triple labour, acardiac twin, 428
 Tule, *Palmaria*, calculus in the, 177
 Tuberculin, the lungs of one of the earliest patients treated by, 437
 Tuberculosis, acute, of the broncho-pneumonic form, 31; and diphtheria, relation between, 36; primary of the breast, 45; of the submaxillary gland, 51; and neoplasm of bladder, surgery of hyaline, 314; of the spinal cord, 381; intra-articular abscess, 332; of peritonsils, disappearance after oophorectomy, 380; laryngeal, surgical treatment of, 406; transmission of through the placenta, 430; articular treatment of, 434
 Tumour, fetal, impeding labour, 180; congenital sacral impeding labour, 431
 Tumours, hydatid, surgical treatment of, 9
 Twin, acardiac, in triplet labour, 428
 Twinbearing, heredity of, 386
 Twin labour, placenta praevia centralis, 388
 Typhoid antitoxin. See Antitoxin
 Typhoid fever. See Fever, enteric

U

Uter, gastric, treated by scraping and dilating the pylorus, 54; perforating line, treatment of by core stretching, 404; gastric, followed by subdiaphragmatic abscess, 4-5
 Uterus, open air treatment of whooping-cough, 36; dermoid ovarian cyst of unusual size, 403
 Uterer, abnormal termination of, in the female, 118; parametric structure of in fatal eclampsia, 389
 Uvula, traumatic rupture of the, restoration of after thirty-six years, 387
 Uvulitis, chronic, treatment of, 345
 Urea and its solvents, 146
 ----- distaste, the, 146
 Urine, retention of in a fetus, 14; suppression of after surgical operation, saline irrigation in cases of, 114; treatment of nocturnal incontinence of, 335; toxicity of the in various, 369; infection from, 370; the reaction of sulphonal in the, 330; the clinical value of the

phenyl-hydrazin test for sugar in, 320; bacteria in the in typhoid fever, 411; a new method of estimating albumen in, 435
 Uterine treatment of itching in, 368
 Uterus, single, double vagina, hematocolpos, 14; vaginal extirpation of after labour, 31; syphilis of, and its appendages, 32; edema and prolapse of cervix of in labour and pregnancy, 37; cancerous, removal of with resection of bladder and intestines, 114; involution of after labour, 114; cure of disease of by vibrations, 108; non gravid, spontaneous rupture of, 127; removal of the inflamed appendages of or hysterectomy, 128; diadelphs, abortion, incision with pyometra, 181; secondary tuberculous of involving the external os, 194; evil results of ventrofixation of, 198; hematocolpos following amputation of cervix of, 207; foreign bodies in the, 225; bicorns in an aged multipara, 288; perforation of by a degenerate fibroid, 413; the in ectopic gestation, 441; edema and prolapse of cervix of in pregnancy and labour, 464; myoma of, 468

V

Vaccination in whooping cough, 266
 Vaccine immunity, 491
 Vagina, cerum, the action of, 380
 Vagina, double, single uterus, hematocolpos, 14; syphilis of, 19; dilatation of by the tampon ("commixtion"), 43
 Vallard, prophylactic use of serum in tetanus, 40
 Van Nes, serum treatment of diphtheria, 57
 Van Schalek, insomnia in surgery and its treatment, 48
 Vague, cardiac hypertrophy and normal growth, 352
 Varicocele, a new operation for, 441
 Variola, toxicity of the urine in, 309; parasites in, 414
 Vas deferens, excision of for prostatic hypertrophy, 1; division of the for prostatic hypertrophy, 146, 234; suture of the, 146
 Vaseline injections in otitis media, 41
 Veiel, alcohol, 445
 Vibrations, cure of uterine disease by, 135
 Vinegar, use of for arrest of vomiting after the administration of chloroform, 312
 Viscera, abdominal, surgical interference in traumatic rupture of, 564
 Vomiting, a new method of treatment for, 303; after administration of chloroform, use of vinegar for arrest of, 312; uncontrollable of pregnancy, 459
 Vulvitis, nephropexy, 113
 Vulvins, hemiatrophy of the tongue in suboccipital caries, 47

Vulva, wounds of from falling astride, 54
 Vulvitis in infants, perimetritis from, 317

W

Wahlstrom, disappearance of tuberculosis of the peritoneum after oophorectomy, 386
 Walke, puerperal tetanus, 364, 368
 Warman, anaesthesia in obstetrics, 349
 Weiss, contaminated ice and cholera, 62
 Welch, the antitoxin treatment of diphtheria, 332
 Wells, internal use of cocaine in whooping-cough, 172
 Wendelstadt, serum treatment of diphtheria, 36
 Wertheim, uterine gonorrhoea, 36
 Wharton, dislocation of the ulnar nerve at the elbow, 69
 White, J. W., indirect operative treatment of prostatic hypertrophy, 149; a new use for thyroid extract, 376
 ----- M. C., the red blood corpuscle in legal medicine, 404
 Whooping-cough, open air treatment of, 36; internal use of cocaine in, 143; vaccination in, 266
 Wiedow, lactation statistics, 138
 Williams, deciduoma malignum in America, 154
 Williamson, the clinical value of the phenyl-hydrazin test for sugar in the urine, 320
 Winkel, endometritis, 82
 Winter, hernia after ovariectomy, 163
 Wittmaier, subdiaphragmatic abscess following gastric ulcer, 418
 Wüller, abnormal termination of the ureter in the female, 119
 Wolfe, trional as a hypnotic, 374
 Women, casein in the milk of, 373
 Workmen, health of in seasons, 347
 Worms, diabetes, 281
 Wossido, castration for hypertrophied prostate gland, 323
 Wróblewski, casein in woman's milk, 373

Y

Yeast fungus, pathogenic, 47

Z

Ziegelroth, danger of amateur massage in gynecology, 347
 Zimmerman, serum treatment of malignant disease, 452
 Zirm, a new treatment of keratitis with hypopyon, 423
 Zorin, keratomycosis in an infant the subject of congenital hemorrhagic syphilis, 317
 Zoster, treatment of, 469
 Zum Busch, thyroid feeding, 264

LONDON: SATURDAY, JULY 6, 1895.

HUNTERIAN LECTURES

ON THE

EXPERIENCE OF ST. GEORGE'S HOSPITAL. IN LAPAROTOMY:

EXCLUSIVE OF GYNÆCOLOGICAL OPERATIONS.

FROM 1888 TO 1894 INCLUSIVE.

Delivered at St. George's Hospital Medical School

By T. HOLMES, F.R.C.S.,

Consulting Surgeon and Treasurer to the Hospital.

LECTURE I.—LAPAROTOMY FOR INJURY; EXPLORATORY FOR ABSCCESS AND FOR PERITONITIS.

THE object of these three lectures is to exhibit the entire experience of a metropolitan hospital, during seven years, of abdominal section, performed on ordinary surgical indications, omitting the operations of gynecology¹ for reasons of convenience, and omitting such operations as enterostomy, gastrostomy, and inguinal colotomy, in which, though the peritoneal cavity is opened, the operation itself is of inferior relative importance, and is to be regarded rather as a step in the palliative treatment of a necessarily fatal disease.

The operations which are recorded are 110 in number, and of these 68 died and 42 recovered. It is not asserted that the list is entire. Some successful cases may have escaped record under the scheme of registration now in use, since these cases are sometimes transferred from physician to surgeon, and sometimes not. And some of the surgeons of the hospital have more or less distinct recollection of successful cases which I have been unable to find. But all deaths are registered in the *post mortem* books: and as I have carefully searched those books for the seven years in question, I have no doubt all the fatal cases have been enumerated.

I was anxious to produce an unselected and continuous series of hospital cases of this kind, which I believe has not hitherto been done, for these reasons. We are inundated in the medical papers with successful cases of laparotomy for various conditions, and from this state of things two opposite conclusions seem to be drawn. Some seem to think that you have nothing to do but lay open the abdomen, and all difficulties will vanish—the patient will get well, and “live happy ever after,” like the end of an old 3-vol. novel. Others of a less credulous or enthusiastic turn reflect that published cases have been published because they were successful, and if they had not succeeded would never have been heard of; that even when distinguished surgeons give their whole experience, that experience represents the practice of a specialist who is called in precisely because the case is a promising one, and who would neither desire nor be allowed to operate unless the case were promising. The unselected and complete experience of a hospital into which a man is sent, not because his case is promising, but too often because it is hopeless, would, as these critics think, tell a very different story. And no doubt they are to a great extent right. No continuous series of hospital cases can be expected to give such good results as the experience of private practice, for the very reason so often pointed out, that the private practitioner is obliged to reject the worst cases, while the hospital surgeon, if he does his duty, must take even the faintest chance of saving life; nay, sometimes, as in railway injuries, has to operate without any chance of

saving life, but merely in the hope of procuring for his patient an easier death. Such a series then cannot be expected to show any high proportion of cures. The indications for laparotomy vary, as you will see by the sequel, from cases in which the whole of a pretty long series will prove uniformly successful, to others in which all of a similar series are uniformly fatal, and the cases are often sent into hospital after all rational prospect of cure is over. But one thing we may say, that nearly every case so operated on would, in times so recent as my own election on the staff of this hospital, have proved fatal; so that we are entitled to rank every success as a gain, while the failures are indeed to be deplored; or, what is much better than deploring, are to be used in order to see how to prevent them in future. Still they are no loss. Failure is only what was inevitable in every condition of surgery known to us hitherto.

It will be seen as we go on that the event of the case was decided almost always by the nature of the disease and the state of the patient; and that the operation of laying open the peritoneal cavity freely enough for adequate surgical exploration and manipulation, formidable as it looks and doubtless is, may be undertaken with tolerable confidence, that is, will not at any rate prejudice the patient's chances, provided he is fairly strong—that in our long list of cases few if any have died earlier than they would have done had laparotomy not been performed; while, on the other hand, there are many cases in this list which did prove fatal, but which would in all probability have recovered had the operation been done earlier. And I will add that I have found many cases in our *post-mortem* books where no operation was performed, in which any surgeon would say that the patient would have had a far better chance if it had been. And that this has been the view of my colleagues I cannot doubt when I see how much more frequent laparotomy has become in the later than the earlier of these seven years, the number rising from 7 in the year 1888 to 26 in the year 1894, a figure which will, I believe, be largely exceeded this year.

The cases are distributed as follows:—

	Cases.	Re- covered.	Died.	
Injury	3	0	3	
Exploratory	5	3	2	
Abscess	11	10	1	
Peritonitis	6	1	5	
Tuberculous peritonitis ...	7	7	0	
Peritonitis from twisted ovarian pedicle	1	1	0	After ovariectomy.
Perforation of appendix, etc. ...	10	0	10	
Removal of appendix	3	2	1	
Hydatids	0	4	2	
Pancreatic cyst	1	1	0	
Hydrocephalus	1	1	0	
Uterine	2	1	1	Exploratory operations for tumours which turned out to be uterine. One re- covered after hysterec- tomy.
Other tumours	5	1	4	
Gastric ulcer and duodenal ulcer ...	11	4	7	
Cholecystotomy	3	2	1	
Gastrojejunostomy	0	3	0	
Isthmusection	5	0	5	
Kink and volvulus	0	1	0	
Strangulation by bands	11	0	11	
Stricture of bowel	2	0	2	
Internal hernia	4	1	3	
Gangrene of caecum	1	0	1	
Total	110	62	48	

¹ Three gynecological operations are recorded in the sequel, which were commenced as exploratory laparotomies.

I shall speak first of laparotomy on account of traumatic injury. One of the most striking of the many advances which surgery has made in my day is in the successful operative treatment of traumatic injuries of the abdomen, which when I was young were universally regarded as necessarily fatal and which therefore received no efficient treatment, and uniformly ended in death. Rupture of the bladder into the peritoneal cavity and rupture of the intestine from contusion of the abdominal wall are good examples of such lesions.

If I am not mistaken, Mr. Croft had the distinction of having been the first surgeon to demonstrate (as Mr. Battle says) that traumatic rupture of the intestine without external wound could be cured by surgery. He published in the *Clinical Transactions*, vol. xxiii, a most striking and instructive paper on this subject founded on two cases in his own practice, in the former of which (ann. 1887) he had established an artificial anus by stitching the ruptured portion of the bowel to the abdominal wall. This operation was in itself quite successful, but the patient succumbed after the subsequent operation for closing the artificial anus. Mr. Croft in his second operation (ann. 1889) resected the lacerated portion of the intestine with its mesentery and a portion of the injured omentum, and the boy perfectly recovered, though at the time of the operation (fifteen hours and a-half after the accident) peritonitis was unmistakably present, and there was a large quantity of fecal fluid in the peritoneum.

A very good example of the feasibility and success of such an attempt is recorded by a surgeon bearing the honoured name of Nélaton in vol. xviii (1893), p. 600, of the *Bulletin de la Soc. de Chir. de Paris*. The man had been kicked by a horse about sixteen hours before the performance of the operation, and peritonitis had already commenced, yet he recovered completely.

There is also a very interesting paper in the *Bull. de la Soc. de Chir.* 1893, p. 247, in which a successful case under M. Michaux's care is related, and reference is made (as in Mr. Battle's paper) to seven successful cases. Two of them were operated on by the same surgeon (Jahoda, of Vienna), and in one of them the operation was performed as late as twenty-five hours after the accident, when peritonitis had been fully developed. Of course the sooner the diagnosis can be established and the operation performed the better will be the patient's prospect, but it is interesting to know that the lesion can be dealt with successfully at so late a period after its occurrence as twenty-five hours.

The total number of published cases appears to be twenty-nine, taking Mr. Croft's and Mr. Battle's lists together. That seven of these should have been saved from otherwise certain death is surely an encouragement to deal boldly with such cases in the future.

Our experience during these seven years of laparotomy for ruptured bowel is confined to two unsuccessful cases. The first patient was a boy, aged 8, under Mr. Haward's care; the symptoms were not very marked, and the operation was not performed till next day, twenty-two hours and a-half after the accident. The lesion in the intestine was not detected, though the bowel was carefully traced up from the ileo-caecal valve. It is a matter of interest to note that the boy did well for five days after operation, when it became necessary to remove the sutures of the abdominal wound, and substitute strapping. The wound burst open, and a coil of gut protruded. This was replaced, and the wound again closed, but he sank rapidly, and died in two days from acute peritonitis. On *post-mortem* examination a rent was found in the small intestine some 3 feet above the ileo-caecal valve, which it is permissible to conjecture had been closed by the protrusion of the mucous membrane till the disturbance caused by the breaking down of the wound. At any rate, at the operation nothing but a small quantity of blood was found in the peritoneal cavity; and this doubtless proceeded from the rupture of the spleen, the preparation of which is before you. This preparation is of interest as showing this lesion practically cured by the adhesion of the spleen to the serous surface of the diaphragm; and it leads us to the question whether in future some cases of more extensive laceration of the solid abdominal viscera may not be rescued from death by free exposure of the rent and packing the abdominal cavity with gauze.

² The Medical Society's *Transactions*, vol. xxvi, p. 274.

With reference to the latter point, you will find in the *Lancet* for March 2nd, 1895, a most interesting case of inflammation and suppuration of the gall bladder, leading to its perforation, in which Mr. Shield operated with success. The gall bladder was freely laid open and the wound packed with antiseptic gauze. In this instance the tissues of the gall bladder were so thickened and so rotten that it was impossible to unite the edges of the ulcer by means of sutures, while the patient's condition did not admit of the total removal of the organ.

The second case, again, illustrates the difficulty which often besets the diagnosis of rupture of the bowel. A man, aged 50, was thrown off his cab when drunk, and the wheel passed over his belly. He was complaining of much abdominal pain when admitted. The urine was drawn off. Next day he became suddenly much collapsed, and an operation was performed when in *extremis*. Incision above the pubes opened a cavity containing foul-smelling fluid, which was thought to be urinous, and therefore the bladder was opened by an incision in the perineum, but was found to be uninjured. After death the laceration was found to be in the small intestine, and was an inch in length.

The statistics of the published cases of laparotomy for intraperitoneal laceration of the bladder are given in a recent volume of the *Annals of Surgery*. They show a total of 29 cases, 12 of which recovered. In one of these, however, the particulars are so loosely given that it is uncertain whether the lesion was not extraperitoneal.

Our experience of laparotomy for uncomplicated intraperitoneal rupture of the bladder during the period covered by these lectures has been nil. In a case under Mr. Turner's care, where a poor boy, who had fallen in climbing a tree, had his bladder perforated from the rectum by a branch which ran through into the peritoneal cavity, it was judged right to perform laparotomy, suture the peritoneal rent in the bladder, and wash the foreign bodies (pieces of twig, etc.) and the vesical and intestinal contents out of the peritoneal cavity; but the case was a desperate one, and terminated in death on the next day but one.

Our experience, then, of laparotomy for injury during these seven years has been very slight, and is purely negative; but I thought you would pardon this short reference to it, for the subject is an important one, and though the cases are rare, a life may occasionally be saved by timely operation, which would be sacrificed by refusal, or even delay, to operate. I have met with one case, at any rate, in our *post-mortem* book, during the period under review, of ruptured intestine, in which no operation was performed, yet which, to judge by the description, was very similar to some of those which have been treated with success.

Turning now to cases in which the peritoneal cavity has been opened in the attempt to remedy the effects of disease, the first class which I will select is that of operations undertaken as exploratory measures.

We have lately heard much about the unjustifiable nature of exploratory laparotomy; and, no doubt, all operations, and especially so grave a one as the free exposure of the peritoneal cavity, must be justified by some rational and adequate motive. In order to exempt the surgeon from merited blame; but as far as our experience goes such operations are (always under this condition) perfectly justifiable, for the only operations which turned out to be merely exploratory, that is, in which nothing was found, were followed by complete recovery. One, under Mr. Bennett's care, was an exploration of the kidney, in which the woman suffered from purulent urine, and was thought to have a movable kidney; another was in a case of Mr. Dent's of supposed impacted gall stone, and a third case was under Mr. Pick's care a few months ago, in which laparotomy was undertaken to ascertain the existence of perforation of the stomach. No perforation was found. The patient completely recovered.

The two following operations might possibly be classed as purely exploratory, since nothing was found at the operation; but they differ from the above cases of recovery in the essential particular that a real and necessarily fatal cause of death existed.

The first was a woman, aged 41, a patient of Mr. Pick, who had had symptoms of obstruction for three days. On cutting into the peritoneal cavity, nothing was found to account for

the symptoms; but on *post-mortem* examination the cause was discovered to be gangrene of the small intestine caused by a thrombosis of the mesenteric vein from vegetations on the cardiac valves.

Another case was that of a woman suffering from ascites, and in whom a tumour was thought to be felt. The operation was performed as a last resource by Mr. Dent to discover the nature of the supposed tumour. The case had been taken to be either malignant disease of the liver or enlargement of the gall bladder from impacted gall stones. Exploration led to the conclusion that it was malignant, but on *post-mortem* examination it turned out to be a cirrhotic liver, the diagnosis not being finally established till after microscopic examination. The tumour perceptible externally was the displaced spleen. She never rallied.

I think, then, we may say that exploratory operations seem rarely to prejudice the patient's prospect of recovery, and I am sure that a careful study of our *post-mortem* book would lead to the discovery of many cases where such an operation would very probably have led to effectual surgical interference.

The next class of which I shall speak is that in which from whatever cause a limited abscess-cavity is found in the peritoneum. The most familiar instance is that of hepatic abscess; but our list contains cases also of abscess around the caecum coli, abscess due to perforation of intestine in which the suppuration has been limited by adhesions, and abscess lying behind the peritoneum and external to it, but only to be reached by opening that cavity and draining the abscess through it. These cases may be treated with almost certain success—if we can trust to our experience hitherto—by laparotomy with drainage, the walls of the abscess cavity being attached to the wound so as to prevent the escape of its contents into the general peritoneal cavity. The following table shows the nature of these cases:

Laparotomy for Limited Abscess.

Name.	Age.	Date.	Nature of Abscess.	Surgeon.	Result.	Remarks.
1. — M	—	June, 1869	Peritoneal	Mr. Bennett	P.	It is doubtful whether the peritoneum was opened or not.
2. (M.)	19	June, 1869	In peritoneum containing a fecal concretion	Mr. Pick	P.	This must have proceeded from perforation of some bowel, which had healed.
3. H. W.	29	July, 1891	Hepatic	—	P.	—
4. (M.)	2	Sept., 1890	—	Mr. Haward	R.	—
5. — P. M.	25	June, 1891	In right iliac fossa	—	R.	Appendix intact, but adherent to caecum.
6. J. B.	29	Nov., 1891	In peritoneum	Mr. Pick	R.	—
7. —	—	— 1892	Abscess from perforation	Mr. Bennett	R.	Detailed notes lost.
8. S. J.	32	— 1892	Peritoneal	—	R.	—
9. J. B.	—	— 1892	In peritoneum	Mr. Pick	R.	Thought to be due to perforation
10. H. M.	29	Oct., 1891	Behind peritoneum	Mr. Bennett	R.	The displaced bladder was accidentally opened in reaching the abscess, and sutured.
11. J. M.	59	Aug., 1891	—	Mr. Shield	D.	The man was dying when admitted; the sigmoid flexure had been perforated by the abscess.

The rest of the operations in this section were undertaken for peritonitis; but these must be further subdivided into those in which the peritonitis was traumatic or "idiopathic"—that is, unaccompanied by any intestinal lesion—and those in which it depended on perforation of some viscus—commonly the appendix caeci. They are tabulated thus:

Laparotomy for Peritonitis.

Name.	Age.	Date.	Nature of Case.	Surgeon.	Result.	Remarks.
1. A. E.	29	Aug., 1890	? From injury	Mr. Dent	D.	Early peritonitis; recent hemorrhage behind the peritoneum round the head of the pancreas.
2. F. M.	30	Oct., 1890	Adhesions from peritonitis	Mr. Haward	R.	Adhesions binding down the ileocaecal junction of bowel; much pain in walking, this was quite cured by freeing the bowel.
3. E. V.	—	Sept., 1890	Acute peritonitis	—	D.	Old adhesions tying down the intestines.
4. J. J.	41	Jan., 1891	—	Mr. Pick	D.	—
5. — G.	74	Feb., 1892	—	Mr. Dent	D.	Old adhesions, ileocaecal junction.
6. L. L.	8	Sept., 1890	—	—	D.	Abscess below the umbilicus; the caecum was the cause.
7. A. E.	21	Sept., 1891	Tuberculous peritonitis	Mr. Dent	P.	Tuberculous peritonitis with fecal concretions in the small intestine.
8. T. G.	—	July, 1891	—	—	D.	There was also pneumonia.
9. — F.	Adult	— 1891	—	Mr. Pick	R.	—
10. — F.	Adult	— 1891	Diffuse peritonitis from tuberculous ovarian pedicle	—	R.	Exploratory laparotomy; the tumour removed after ovariectomy.

The next class of cases are those in which peritonitis is caused by perforation of the vermiform appendix or some other portion of the bowel which remains open, for we have seen that in some cases the perforation closes, leaving a limited peritoneal abscess.

Now in such circumstances it seems obvious that the patient has a far better prospect of surviving if the nature of the case, that is, the perforation, is ascertained at the operation. If the appendix be the seat of the lesion, it can easily be removed, and with fair prospect of recovery. If the perforation be in another part of the bowel, no doubt its operative treatment is not so easy; but in some cases the neighbouring part of the bowel may be healthy enough to allow of the suture of the edges of the ulcer, as in the successful case reported by Mr. Lockwood²; otherwise the surgeon's choice would lie between resection of the diseased part and the formation of an artificial anus.

But it is by no means easy to detect these perforations; in some cases it is not even easy to recognise the appendix, which is pushed away and hidden under masses of lymph and pus; so that a deliberate search is necessary, which must often be impossible if the operation has long been delayed.

I find 9 fatal cases reported in which perforation of the appendix existed, but was not discovered till after death. In 4 at least of these cases the operation had been postponed till an attempt thus deliberately to examine the conditions of the organs would have been impossible.

In a tenth case the perforation was in the small intestine; it depended on tuberculous mischief, and there were other complications which rendered successful treatment hopeless.

I find it most difficult to judge what the success of laparotomy hitherto has been when undertaken for the purpose of treating diffuse peritonitis. The most recent information on this subject has been given us by Mr. Lockwood³ in a paper

read and discussed at the Medical-Chirurgical Society October 23rd, 1894. This paper is founded on three successful cases, of which one was due to perforation; the others would, I think, be classified as "idiopathic." These cases are said to have been the only instances of recovery after laparotomy for diffuse septic peritonitis in St. Bartholomew's Hospital or

² Med.-Chir. Trans., vol. 76, p. 2.

³ Med. Chir. Trans., vol. lxxviii, 1.

the Great Northern Hospital up to that date; nor do I see that any of the speakers in the debate which followed referred to any others.

Fatal Cases of Diffuse Peritonitis from Perforation.

Name	Age	Date	Duration of Illness	Part Perforated, Found or Not	Surgeon	Remarks
F. H.	26	Sept., 1890	12 days	Appendix cured not found	Mr. Pick	This operation had been too long postponed, but was done at once after admission.
A. F.	15	June, 1890	5 "	"	?	Operation immediately after admission.
A. (W.)	44	Jan., 1891	3 "	"	Mr. Turner	The peritonitis had resulted from bursting of a peritoneal abscess into the peritoneum.
M. M.	17	May, 1891	2 "	"	Mr. Dent	Two bands of adherent omentum were divided at the operation. Probably this prevented a careful examination of the bowels.
W. L.	21	April, 1890	6 "	"	Mr. Pick	This operation was done at once, but too late.
G. F.	—	May, 1891	3 "	"	Mr. Haward	Operation at once. He was too collapsed to bear much manipulation. Several collections of pus existed in the peritoneal cavity.
M. O.	34	May, 1891	1 "	"	Mr. Bennett	In this case also the operation was immediate, but she was too far gone. She had had symptoms more or less severe for a fortnight, but was at work three days before admission.
H. J.	26	Aug., 1890	5 days before admission	"	Mr. Pick?	Operation only performed two days after admission, when in extremis.
F. C.	26	June, 1891	7 "	"	Mr. Bennett	The symptoms were those of peritonitis. Exploratory operation two days after admission failed to detect the cause.
A. G.	2	May, 1890	7 "	Small intestine perforated from rupture of a peritoneal abscess	Mr. Dent	He survived the operation nine weeks, and died from general wasting.

Yet I suppose many cases of alleged success have been published, for a paper on Abdominal Section for Peritonitis by a Russian surgeon is abstracted in the *Annals of Surgery*, 1891 (vol. xiii), in which reference is made to 24 cases of laparotomy for "idiopathic peritonitis," in 10 of which recovery is claimed. The references, however, are not given, so that the cases could not be followed without great labour, and I must say that the result would not repay the trouble. No such ratio of success can reasonably be anticipated in any continuous series of cases. But Mr. Lockwood's and other published cases may encourage us in attempting the operative cure of the disease; and the suggestions which he gives for the details of operation seem eminently calculated to assist the operator in obtaining success.

I must allow that in looking over this series of cases the difficulties which stand in the way of success in the operative treatment of diffuse suppurative peritonitis come strongly before me. When the inflammation is purely traumatic I cannot doubt that the free irrigation and drainage of the peritoneal cavity will succeed in a large proportion of cases, but they are rare. No instance has been put on record here in these seven years. When the cases are classed as "idiopathic," this can only mean that the cause has not been discovered, and we cannot therefore feel much confidence either

that incision and drainage will remove that cause, or will enable the patient to survive its continued action. Tuberculous peritonitis seems to me to hold out but a poor prospect of permanent recovery, though a large proportion of cases are noted in the paper just referred to, in which the patient has survived the operation, and there is one such case in the foregoing list; but the list of cases just produced shows in how large a proportion the peritonitis is caused by perforation, especially of the appendix; and it shows also how liable the surgeon is to overlook such perforations, and this must be much more frequently the case if the operation is delayed till the patient is in extremis, and unable to bear a prolonged and exhausting search amid the contents of the abdominal cavity. If the surgeon will bear in mind the frequency of ulceration of the appendix, which is covered and concealed by adherent intestine and masses of lymph, and if there is the opportunity for that deliberate separation of the intestines from each other which Mr. Lockwood recommends, the source of the peritonitis could be discovered and removed, and the patient's chance of survival indefinitely increased.

This course was pursued in three cases, with results which are encouraging as far as so small a number permit of any deduction, two of them having recovered after the removal of the perforated appendix.

THE CROONIAN LECTURES.

CONTRIBUTION TO THE HISTORY OF THE RESPIRATION OF MAN.

Delivered before the Royal College of Physicians of London.

By W. MARCET, M.D., F.R.S.

LECTURE III.

MR. PRESIDENT AND GENTLEMEN,—In my last lecture the first three forms of breathing were considered. Let us now proceed to the fourth, which applies to respiration under the influence of volition; but before doing so allow me to recall the remarkable experiment of Professor Mosso, of Turin. This gentleman constructed a metal instrument, a sort of glove, through which his fingers were inserted, with the exception of the middle one; with this finger he worked a weight up and down until the digital muscles concerned in the labour were completely exhausted; at this stage the muscular contraction was carried on by means of electrical excitation, and he found that if, after a short period, the excitation was discontinued, the finger was able still to maintain its work, showing that the muscles had not ceased contracting from actual fatigue, but from exhaustion of the will which had been exercised to move them.

There is an interesting borderland between psychology and physiology which is narrowing daily. The discovery of the electrical excitability of the brain by Fritsch and Hitzig, and of the motor centres by Ferrier and Yeo, followed by Horsley and Schäfer, has opened altogether a new field of research, and brought the mental and physical functions nearer to each other. We do not know much of the physical effects exerted on the body by the perception of our senses. Moleschott, as far back as 1855, showed that from one-tenth to one-fourth more carbonic acid was exhaled by frogs under the influence of light than when in the dark, and also that this increase varied directly as the intensity of the light, which acted through the eyes and skin.

It occurred to me that if light exercises a distinct physical action on the living body, perhaps sound would produce a similar effect; but even a fairly loud sound, such as that produced by the beating of a gong close by, gave no positive result; the carbonic acid emitted under the influence of the sound being sometimes a little more and sometimes a little less than normal, and the same could be said of the oxygen absorbed. There was, however, a slight excess of air breathed (expired) while the noise was continued, which varied from 0.036 litres to 0.723 litres per minute in eleven experiments; and this slight excess was balanced by a corresponding diminution of the volume of air exhaled during the first five or six minutes after the sound had ceased.

The perceptions of our senses are certainly independent of our will, still the sight and hearing may not be entirely unconnected with volition; or it would, perhaps, be more correct to say that objects may act on the brain through sight, and sounds through hearing, without producing any corresponding impression. Take the case of a person lost in a brown study: he does not see objects though with eyes wide open, nor will he hear a sudden noise.

By submitting our senses to the exercise of volition, we train them and improve their perception. Thus we train the sight to the better appreciation of the beauties of Nature. Those thrilling descriptions of Alpine scenery must be the outcome of the training of the sight to the thorough enjoyment of mountain views. The rapture into which Sarasate or Joachim throw their hearers requires a certain training of the audition.

Mosso has shown that volition is a cerebral act attended with fatigue. I need hardly remind you of the fatigue experienced in listening to good music: two hours thus employed will, as a rule, be amply sufficient, and it often happens that in less time the attention begins to flag and the impression to subside. Operatic music may be listened to much longer, for the obvious reason that in an opera the exercise of volition is distributed between two brain centres—those of hearing and of sight—instead of being concentrated on a single one, and is on that account less exposed to fatigue.

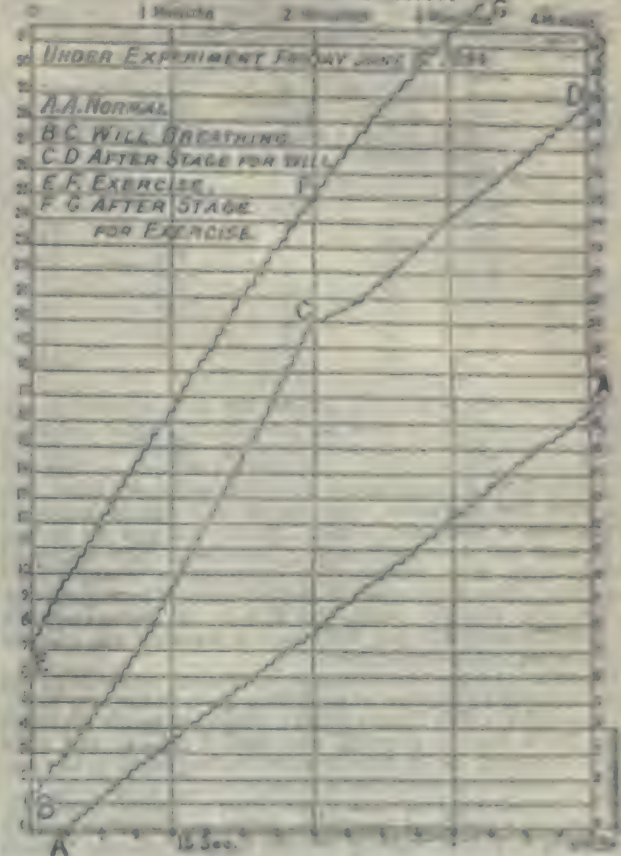

We now come to the influence of volition on muscular movements. There are instinctive muscular movements in which volition is not concerned—for example, those required to balance the body—but these have been acquired in the first instance by the exercise of volition or by training. Hence it appears that training is of fundamental importance in all muscular exercise, such training being at the same time applied to the action excited by the cerebral motor centre concerned in any special form of muscular work. Learning to play on a musical instrument is certainly training volition quite as much if not more, than training the muscles; the surprising rapidity with which the fingers run over the notes of the piano in response to the will is also a case in point, although, if I understand rightly Dr. Bastian's views contained in his book on *The Brain as an Organ of Mind*, it is very possible that such training, especially in young people, should develop a certain set of nerves through which these rapid impressions are conveyed, becoming automatic in their character. We shall see that volition has a direct action on respiration, hence training volition is at the same time training respiration. Let us now pass on to the subject which forms the substance of this lecture—the influence of volition on respiration.

Under ordinary circumstances, when sitting in repose, the mind is at rest as well as the muscles, and the breathing quiet and regular. Should a strong effort of volition be made, although unattended by any muscular contraction, it may be observed to react immediately on the respiration. If after a tracing of normal respiration has been obtained, the person under experiment sets his mind to work and exerts his volition strongly towards carrying a heavy weight, running to catch a train, or pursuing another person uphill, the tracing recorded on the chart will be observed to ascend more rapidly than in the case of mental rest, showing a greater volume of air breathed in the same time. After, say, one or two minutes, let the influence of the will be withdrawn and respiration continued under mental repose; the first effect will be the production of a respiratory pause, the tracing taking a more horizontal direction, as seen in forced breathing, though perhaps somewhat less marked, after which the breathing will return to the normal, the tracing obtained being much like that of forced breathing.

Similar experiments on different persons invariably yielded the same kind of curve on the chart. It follows that the influence of the will is to increase the volume of air breathed, and that on releasing volition a pause is produced very like that which follows forced breathing; but there is this difference with forced breathing, that when the will is applied say to the act of locomotion, the increased pulmonary ventilation is absolutely automatic, while forced breathing is the direct effect of volition applied towards the expansion of the chest.

An explanation of the pause or apnea after forced

BREATHING CHART.

The tracing "under exercise" is shown to contrast with that for breathing "under volition."

breathing is that forced breathing produces an increased absorption of oxygen, and this oxygen being used for the requirements of the body lessens for a few seconds the calls for pulmonary ventilation. This idea suggested that perhaps such an accumulation of oxygen in the body might be employed by the muscles for a temporary increase of power. The following experiment was therefore made: while sitting in an armchair a weight of 10 lbs. was alternately raised and lowered with the hand in keeping with the striking of a metronome, and to my surprise it was observed that after a succession of deep inspirations the weight could be raised a much greater number of times than after normal breathing; indeed, the increase of power was such that the weight could be lifted to the same height before exhaustion perhaps two thirds or twice as often after forced breathing as after natural respiration.

For a time this effect of forced breathing was to me absolutely unaccountable as there was no apparent call for an accumulation of oxygen in the tissues, and no proof of any such absorption; moreover, the excess of carbonic acid formed by the muscular power added was infinitely greater than could be accounted for from any excess of oxygen absorbed in the body. But perhaps in forced breathing there was really an increase of oxygen absorbed, which was taken up by the brain centres of forced breathing, and gave "volition" the power of doing so much additional muscular work through increased respiration. This view was subsequently investigated and its correctness shown, by experimental methods.

Allow me to quote the experiments which show to what extent muscular power may be increased by the preliminary exercise of "volition" exerted in the form of forced breathing. It might be added that in order to succeed with these experiments, the attention or "volition," should be given to the act. It failed once or twice when first tried, though successful on

every other occasion with that same person, probably because the will was not assisted with sufficient power or was not yet possessed of sufficient training for that kind of experiment.

It is remarkable to what extent the arm becomes accustomed to this kind of work, and can develop more and more strength with time from training. This is seen in the figures given later on, but it is important to observe that the present remark does not apply to the experiments taken singly, when the increased work was clearly due to increased power from a temporary cause. This point was set at rest by a very simple experiment. Two consecutive series of liftings were made without the intervention of any forced breathing. The weight was raised till stopped by exhaustion 26 times in the first series and 26.5 in the second; hence it cannot be said that any influence of training was exerted in the comparative experiments.

The effect of forced breathing in increasing muscular power can be tested by anyone while sitting quiet in his own room. My friend Dr. Louis Parkes lifted a weight of 8½ lbs. 50 times while in a state of physical and mental repose; and after forced breathing for 1½ minute, applying his mind to the act, he raised the same weight to the same height 125 times.

A lady reclining in an arm chair lifted with her right arm a tea kettle weighing 4 lbs. 13 ozs. 60 times, and after resting ten minutes and breathing forcibly for one minute, raised the same teakettle 100 times to the same height.

The greatest effect was produced on a medical friend, who after ordinary breathing lifted a weight of 4 lbs. 203 times in succession, and after a rest and forced breathing for two minutes lifted the same weight the same height no fewer than 700 times. In this case volition taxed the muscles to the utmost, and the arm remained tired and stiff for some days afterwards. The weights in all these experiments were lifted under natural or automatic respiration after forced breathing had been discontinued.

The absorption of an excess of oxygen in the body under forced breathing was so far an assumption, and it became necessary to determine experimentally if such were the case; the methods in use for the determination of carbonic acid and oxygen in the expired air being extremely delicate, the results obtained may be looked upon as thoroughly reliable.

The experiment was undertaken in the following way. After resting for some time in the arm chair the expired air in normal breathing was collected for subsequent analysis, then forced breathing was taken for about two minutes and the air expired collected separately. As soon as the appointed time had elapsed a signal was given, and the person under experiment relapsed suddenly into automatic breathing, while at the same time, by means of a three way stopcock, the air expired was diverted into a third receiver, breathing being continued until it had come back to its normal condition in repose, which took place within six or seven minutes. There were thus three samples of air for analysis. The volumes of air inspired in each stage were calculated, as previously explained, from the nitrogen found, which underwent no change; the volume of nitrogen obtained yielding by a simple proportion the volume of air inspired. The difference between the volumes of air inspired and expired (after the application of a correction for carbonic acid emitted from the blood, into which subject it would take too long to enter at present) gave the volume of oxygen absorbed, and it is the excess of this oxygen absorbed in the body in

forced breathing over the oxygen absorbed in normal respiration which concerns the present question.

In eight experiments, the increase per minute above the normal of oxygen absorbed under forced breathing, or rather under volition for forced breathing and response, varied from 0.6 to 39.4 c.cm. with a mean of 13.9 c.cm. (53.0 c.cm. — mean absorbed normal and 67.3 mean absorbed under forced breathing). At the same time the volumes of air expired were greater under forced breathing by 69 per cent. of normal. Therefore, in these experiments considerably more air had been inspired, and there was a marked increase of oxygen absorbed.

If the excess of oxygen absorbed in forced breathing has for its objects the exercise of volition, surely this absorption must take place in the motor centres of the brain concerned in forced breathing, and, therefore, in the medulla oblongata. So far the argument stands thus—forced breathing is accompanied by an excess of oxygen absorbed in the body and leaves in its wake increased muscular power, but this excess of oxygen absorbed is very insufficient to account for the increase of CO₂ produced, hence it does no such thing. Nothing, therefore, is left to explain the excessive development of power but an increased effect of volition, brought about by the absorption of an excessive amount of oxygen in its motor centre, which is in the present case the motor centre of respiration.

This is a new departure, and one which appears to me fraught with interest. If the exercise of the will necessitated the absorption of oxygen in forced breathing, it was natural to conclude that the exercise of volition for forced breathing though without response would be attended by a similar result; and, if so, it should also produce an increase of muscular power as observed after forced breathing.

BREATHING CHART.

This reasoning gave rise to the following experiment. When in a state of mental repose I lifted a weight of 10 lbs.

42 times to a height of 18 inches, after which the arm became too tired to continue the work. After a sufficient rest the will was applied to forced breathing, but without response, for two minutes; and on suspending its action I was able to lift the weight 76 times, being an increase of 34 liftings.

A similar experiment with another person gave 70 liftings for normal, and 96 after the exercise of volition towards forced breathing without response; therefore, in both these instances, the increased development of muscular power was clearly the effect of volition only. The proof that the effort of volition in the present case was unattended with response is to be found in the form of the tracing obtained.

When volition attended with response is exerted towards forced breathing, the record on the chart invariably shows a pause or state of apnoea on returning to automatic breathing in repose; but when volition towards forced breathing is unattended with response there is no pause, or the pause is barely appreciable, as seen in the second chart on page 6. The same experiment was repeated with volition applied to various other forms of exercise, and an increase of power was invariably obtained; thus after volition for running without response I raised a weight of 8½ lbs. 77 times against 47 for normal. This increase of power must have been produced through the agency of the respiratory centres, as whatever be the form of volition it must supply the oxygen necessary for the heat required towards the increased muscular exercise.

If, after exerting volition without response, greater development of muscular power is obtained in the same way as when exerting volition towards forced breathing, and if the latter is, as I have shown, attended with an increased absorption of oxygen, it appeared probable that an excess of oxygen would also be absorbed under volition, though without response, exerted towards various forms of muscular exercise, and a number of experiments were made which showed most conclusively that such was the case.

In a first series of seven experiments, the will being applied without response to running or rowing, the excess of oxygen absorbed in four of the seven experiments varied from 7.7 c.c.m. to 19.4 c.c.m. per minute, with a mean increase of 12.4 c.c.m. per minute, while in two of the other three there was a slight decrease in the volition stage by 2.1 c.c.m.; one of these, however, showed an increase in the after stage, as if in this case the oxygen in excess had been taken in the first instance from that in store in the muscles and other tissues, and returned from the atmosphere on the resumption of mental repose. On releasing volition and relapsing into normal automatic breathing, the mean oxygen absorbed was less than normal, the deficiency compensating very nearly the excess taken in under volition. Therefore, after the phenomenon was over the absorption of oxygen had apparently undergone no change or combination in the motor centres.

The oxygen absorbed was now determined on three different occasions after applying the will without response towards lifting a heavy weight, the results in these cases were well defined. In one experiment the excess of oxygen absorbed per minute under volition was 15.6 c.c.m., in another 13.8 c.c.m., and in the third 35.8 c.c.m., with a mean of 21.7 c.c.m. The oxygen absorbed in the after stage again very nearly compensated the excess under volition. This series, though consisting of only three experiments, therefore confirms the former in every way, and shows that volition towards lifting a weight causes an accumulation of oxygen in the body, clearly in the motor centres of the muscles of the arm. A third set of six experiments was made by applying volition without response towards forced breathing. The increased absorption of oxygen in the volition stage varied from 1.5 c.c.m. per minute to 44.0 c.c.m. per minute, with a mean of 23.9 c.c.m., and this excess was also nearly balanced by a corresponding diminution of oxygen absorbed in the after stage. Probably these experiments, in which the oxygen determined "as absorbed" is taken from the air, do not show the total volumes of oxygen absorbed by the motor centres as it is impossible to ascertain how much is supplied from the tissues.

It thus appears that whenever volition is applied towards any form of exercise, there is an absorption of oxygen in the cerebral centres concerned in the phenomenon; and apparently with an excess of oxygen absorbed more work can be done than if the excess be wanting. The following experi-

ment in which a mixture of oxygen gas and air was breathed is a striking confirmation of this view. The author lifted a 10 lbs. weight 41 times before being exhausted. After a rest he exercised his volition strongly towards lifting a weight for 1½ minute, and then raised it 61 times in succession. Again, after another rest, he exercised the same kind of volition as before while inspiring a mixture of two-thirds of air and one-third of oxygen containing nearly 48 per cent. of oxygen, instead of 20.9 per cent. as in atmospheric air; and immediately afterwards lifted the weight 87 times before being arrested by fatigue; therefore under the influence of volition and air twice as rich in oxygen he could lift the weight 26 times oftener than when inspiring atmospheric air the will being applied in a similar manner. This experiment repeated on another person gave with volition and atmospheric air 77 liftings, and under the influence of volition and a mixture of air and oxygen, similar to the previous one, 94 liftings, or an increase of 17 liftings.

Returning to the respiratory tracings under the influence of volition, we find that whether the will be applied without response to locomotion, to manual labour, or to forced breathing with response, the curve is about the same; that is, first the tracing is steeper than normal; then on releasing volition there is a pause, followed by another rise, showing an increased volume of air breathed beyond the normal. One tracing under volition differs from all the others; it is that for volition towards forced breathing without response, when the pause is altogether wanting or hardly visible.

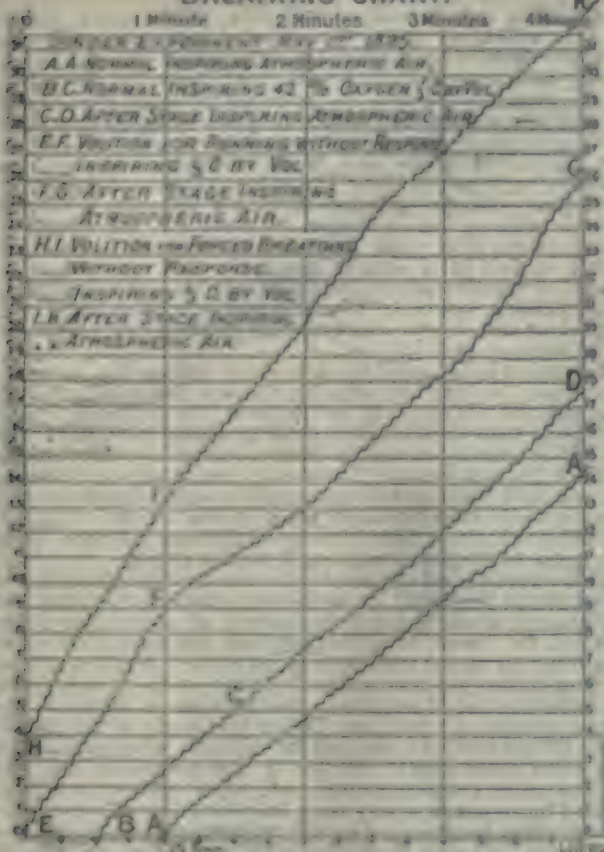

This pause at first appeared to be due to the accumulation of oxygen in the motor centre under the action of volition, but the absence of any pause in the records of respiration under volition for forced breathing without response, even after breathing air mixed with oxygen gas, showed the present view to be mistaken, since this form of volition is also attended with an accumulation of oxygen in the respiratory centres. The only explanation I can now offer for this pause is the following: All the centres concerned in volition, whether they be the motor centres for locomotion or manual labour, etc., act on the centres of respiration; and when volition is accompanied by response, a very large increase of breathing is produced which is controlled by the requirements of the centres concerned. As soon as volition without response is exerted there is no longer any excess of pulmonary ventilation required, and normal automatic breathing follows; but before the centre of respiration has shaken off the influence of the other centres, a short lapse of time intervenes during which the oxygen stored up in the tissues comes into use. This is the reason which appears to me to account for the pause, a view confirmed by the fact that, as shown in the breathing records, immediately after the pause, there follows a slight but decided increase of air inspired beyond the normal, whose object would be to replace the oxygen taken from the tissues. Now in volition towards forced breathing without response when the will is suddenly released no lapse of time is needed as there is only one centre concerned in the phenomenon, that of respiration; hence there is no pause and the tracing returns immediately to the normal. Even if a mixture of two-thirds of air and one-third of oxygen be inhaled whilst volition is exercised towards forced breathing, there is no pause; but a considerably increased pause is observed after inhaling the mixture of air and oxygen, and at the same time applying the "will" to other forms of exercise, as seen in the first chart at the next page.

It might be objected that the oxygen absorbed from the air in natural respiration is possibly liable to change every few minutes and that the increase obtained under volition is due to some other cause than the exercise of the "will." In order to answer this objection the following experiments were made.

Air was expired while in mental repose, and receding in an arm chair, in three successive bell jars, each receiver taking seven or eight minutes to fill. The three samples of air expired were analysed separately and the experiment being repeated on three different days gave the following figures for oxygen absorbed per minute:

Cubic Centimetres of Oxygen Absorbed per Minute.		
Experiment I.	Experiment II.	Experiment III.
1-11.5	1-11.5	1-11.5
8-11.5	8-11.5	8-11.5
1-11.5	1-11.5	1-11.5

BREATHING CHART.

The greatest difference per minute in each experiment was therefore 5.3 c.c.m. in the first experiment, 4.6 c.c.m. in the second, and 3.6 c.c.m. in the third, showing but little change in the oxygen absorbed in three successive experiments and giving much confidence in the method of analysis.

It may therefore be safely concluded that in the experiments on volition it was the effort of the will, and no other circumstance, which increased the volume of oxygen absorbed. Out of 24 experiments there were 3 with an increase of less than 1.5 c.c.m. per minute, and 2 with a decrease of 2 c.c.m. The increase was marked in the other 19. In two series of experiments it amounted to means of 22 and 28 c.c.m. There is no other way of accounting for that increased absorption of oxygen but through the agency of volition. Now, where can that oxygen go to in the body? It cannot remain in the blood, as hemoglobin on leaving the pulmonary circulation is considered as charged with oxygen as it can be. On the other hand, there must be a demand for oxygen somewhere, because, as I have shown in my first lecture, no oxygen is taken into the body unless it be required. Of what use can be that oxygen taken in for the requirements of volition if not to exercise some sort of direct action on the motor centres concerned in volition; a parallel case would be the absorption of increased volumes of oxygen for the performance of muscular exercise, although the mode of action in volition appears to be of a very different character.

The fact that oxygen is required in the body towards volition is shown by the increased volume of air breathed under volition. If this air was wanted for an excess of carbonic acid, we should find an increase of carbonic acid produced. There is indeed a very slight increase, but it is wanted for the extra work done by the muscles of respiration, and there may be some slight oxidation of hydrocarbon in the brain substance, and in some cases it is impossible to find any production in excess of

carbonic acid, this being probably due to physiological irregularities which it is impossible to control. We find, also, a certain volume of carbonic acid displaced from the blood by the increased volume of the air breathed. It might perhaps be objected that out of twenty-four experiments five results failed to agree with the other nineteen; but these exceptions occurred in the early part of the inquiry, and volition had very possibly not been brought to bear so earnestly as it was in subsequent experiments. It is a fact that the more experienced we became—my assistant and myself—in these volition experiments, the greater the volume of oxygen which was found absorbed.

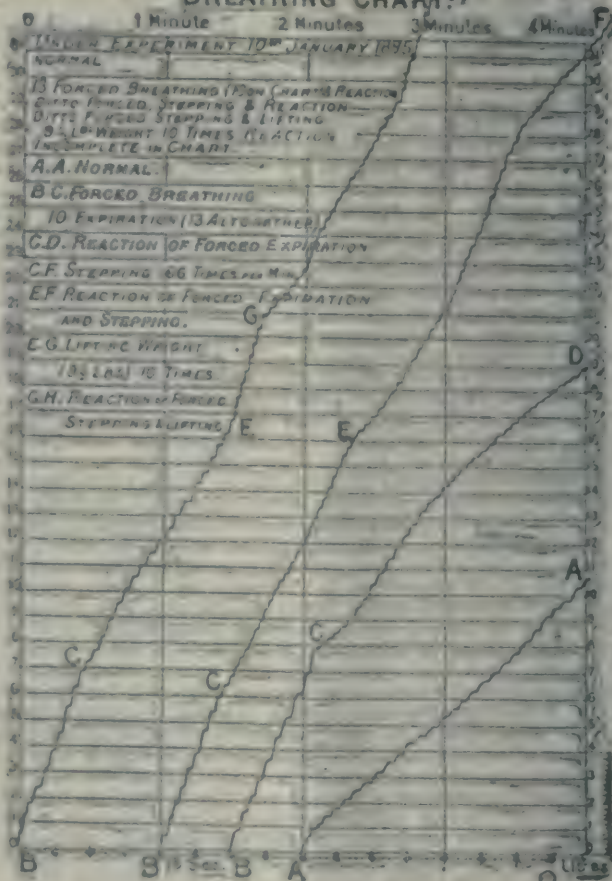

There is evidence in favour of this view in addition to chemical analysis: this is increased muscular power, and I shall again beg to direct your attention to this phenomenon.

If additional power is given to the muscles by a preliminary effort of volition, naturally there must be an increased amount of carbonic acid produced in proportion to the increase of strength developed. Three experiments were made which showed clearly that such was the case. The mean relation of the strength developed was 1 to 1.300, that of CO_2 to CO_2 , while engaged in the extra work was 1 to 1.006; there was not, therefore, much difference between those relations for such a small number of experiments.

If after exercising the will, instead of returning immediately to the state of physical and mental repose the weight of 10 lbs. be raised in the usual way for one minute, followed by repose, while a record of breathing is taken on the chart, the pause which has been clocked by the exercise now appears, and afterwards respiration returns much increased in volume.

Finally, if immediately after the exercise of volition for one or two minutes, stepping exercise is taken for one minute, followed at once by a return to the sitting position, and lifting the weight, say, ten times in succession, on assuming

BREATHING CHART.

the state of rest the pause will again appear, though perhaps less marked, and there will be for a time a considerable increase in the pulmonary ventilation beyond the normal in repose. This is clearly seen in the second chart on page 8 recording the experiment.

If anybody should be still disposed to question my contention that the increased muscular work in these experiments is due to the influence of volition, the experiment of Mosso showing that fatigue of "volition" suffices to arrest muscular contraction would go far to dispel any doubt in that respect. The following experiment, which I have not seen quoted, confirms remarkably Mosso's discovery, while at the same time it is a strong argument in favour of the view advocated in this lecture, and differentiates very clearly the motor centres of the brain.

Let a person, while sitting in an arm chair, raise a weight as in the experiments related above until his arm is too tired to continue the work. He then takes a rest in mind and body of say one minute, and again resumes lifting the weight as long as he can. The number of times the weight is lifted is counted in both cases. Next a rest is taken perhaps for ten minutes, and the same kind of exercise repeated until the arm is exhausted; at the expiration of that time the arm is placed in a state of repose, but the "will" continues being applied as strongly as possible towards the exertion of lifting the weight, and this is continued for one minute. At the end of that minute the weight is again raised with that same arm, when it is found to be so tired that it is not equal to raising the weight by perhaps more than about one-half the number of times the weight was lifted under precisely similar circumstances without the application of the will.

If, however, during the interval of one minute between the liftings, the will be directed towards a different kind of muscular work, such as running uphill, on resuming the lifting, the arm is found to be fresh and rested, and can raise the weight the same number of times as if the mind had been at perfect rest for that minute.

The following are two experiments which illustrate the phenomena:

While reclining in a deck chair, I raised a weight of 10 lbs. 49 times, and gave up from fatigue; after resting for one minute the same weight was lifted to the same height 40 times; a long rest was now taken and the weight lifted 47 times, when the work was stopped by fatigue; then the arm was rested while applying volition as strongly as possible to a continuation of the same effort of lifting for a lapse of one minute. Lifting was now resumed, when the weight felt very heavy and could only be raised 21 times—clearly not because of the fatigue of the muscles as they were rested, but from the exhaustion of the power of volition. A similar experiment on my assistant gave the following results:

Normal liftings, 42; after one minute's mental and physical rest, 41 liftings; after a prolonged rest, 44 liftings; after one minute's physical rest, but with volition exerted towards a continuation of the same exercise, 31 liftings.

The same experiment was repeated by both of us without applying the will towards the continuation of the same exercise, but towards an exercise quite different, such as running, thereby resting the motor centre on which volition had exerted its action towards lifting the weight. After a minute the arm felt perfectly rested and raised the weight the same number of times to the same height as before.

ARTHUR DURHAM MEMORIAL.—The friends, and they are many, of the late Mr. A. E. Durham, have resolved to perpetuate his memory by the endowment of two beds at Guy's Hospital, one in each of his old wards, Lazarus and Martha, to be called the Arthur Durham beds. For this purpose a sum of £2,000 is requisite. Contributions may be paid to Mr. C. H. Wells, at the office of the Medical School, Guy's Hospital; and they will be acknowledged from time to time in the *Guy's Hospital Gazette*. All subscribers of one guinea and upwards will receive a platinum engraving of a life-like photograph of Mr. Durham. The circular asking for funds was posted on June 11th, and in ten days the sum of £283 was collected, being almost one-third of the entire amount that is required.

SELECTIONS FROM MY CASEBOOKS.

By ALFRED SHEEN, M.D.,
Senior Surgeon Cardiff Infirmary

I.

1.—IMPACTED FRACTURE OF THE NECK OF THE FEMUR IN A VERY OLD MAN.

J. H., aged 91, a hawker, was admitted into Cardiff Union Hospital on January 17th, 1893. He had been a heavy drinker all his days, and had suffered from bronchitis for some years.

On admission he stated that he had been knocked down by a cab a few hours before, but was not run over. He could not get up without help, and complained of pain about the left hip, loss of power in the left leg, and great pain on the least movement of the limb. The left foot was everted, the limb lay flat on the bed, and was nearly 2 inches shorter than the right. No definite crepitus was obtained, but great pain was caused by manipulation, and there was thickening about the trochanter.

The limb was steadied by means of extension with pulley and weight, and a large sandbag on each side of thigh. After a few days he was allowed to sit up in bed, and six weeks later was allowed to get up on crutches, and he continued to get about until his death in April, 1894, from acute nephritis. The accompanying reproduction of a photograph of the upper

part of the femur will give a good idea of the displacement and the amount of repair.

II.—LEFT SUBCLAVIAN ARTERY CURVED BY LARGE TUMOR OF LOBBE OF PULMONUM AND KENT IN LUNG.

R. D., aged 38, single, a bookman was admitted to Cardiff Infirmary on March 21st, 1893, with a history of an illness beginning suddenly four years earlier while, under treatment for a wound of the leg. The knee swelled, and he had pains in most of his joints and limbs, attributed to rheumatism. The patient had had these pains off and on ever since. The left arm had for some years been getting weaker. Six months before admission, when rubbing ointment the patient discovered a swelling under the left axilla, but did not seek advice till a month before admission. There was an obscure specific history. He was a fairly healthy man of good physique, just below the left axilla was a smooth pulsatile swelling, the borders of which were not determinable. Palpation ceased

on compressing the subclavian artery. On extending the arm from the side the swelling was distinctly felt in the axilla, and it extended up to and just above the clavicle. The fingers of the left hand were clubbed; the radial pulses were synchronous and equal in volume. The heart was normal but a *bruit* was heard over the tumour, which was the size of a goose's egg.

On April 2nd he was put on iodide of potassium (gr. x) thrice a day. The dose was gradually increased to 5i thrice a day. On April 28th and on May 14th he was put on 3jss thrice a day. This he took with slight intermissions, on account of diarrhoea, till the end of September. On July 23rd it was noted that there had been "no pulsation for at least five weeks." On August 21st he was made an out-patient. He was shown before the Cardiff Medical Society in October, 1884, when there was no evidence of the aneurysm, though the radial pulse was slightly weaker than on the other side. He was able to do his work.

Dr. Walsh, of Clifton, reports a somewhat similar case under his care in the Bristol Royal Infirmary, in 1881. In a farm labourer, aged 40. In his case the treatment was "perfect rest in bed, bandaging the arm to the side, low diet, restricted allowance of fluids and iodide of potassium," gradually increased from 10 gr. to 50 gr. thrice a day. The man left the infirmary four months after his admission, returned to his work, and was quite well one year afterwards. It is not stated whether there was any specific history in this case.

III.—CYSTIC THYROID: LACINATION: DEATH.

E. C., aged 24, single, a collier, was admitted to the Cardiff Infirmary on May 15th, 1884, with a history of a swelling on the left side of his neck, first noticed when he was 15 years old. It had slowly increased in size up to the present time. This illustration gives a good idea of his appearance on

admission. The patient was pale, rather anæmic; the respiration was noisy, except when the patient was quite still. After movement, exertion, or speaking there was marked stridor.

On June 9th chloroform was given and I removed the left half of the thyroid by a long oblique incision. The dissection was carried down to the wall of the largest cyst, and after that dissecting forceps were used almost exclusively for separating the tumour from its surroundings. Veins were

British Med. Jour., Journal.

taken up and tied at frequent intervals; they were numerous and some of considerable size. The whole of the left half of the thyroid was converted into cysts of various sizes, and the part adjacent to the isthmus was of almost calcareous hardness. The dissection occupied about three quarters of an hour. The patient breathed badly if deeply anaesthetised and whenever the tumour was at all drawn outwards. The operation took a little over an hour, and all antiseptic precautions were observed.

The wound was irrigated with perchloride of mercury solution, 1 in 4,000; interrupted silkworm gut sutures were used, a drainage tube inserted at the lower end, the whole dressed with iodoform, green protective, sublimate gauze and wool and bandage. The dressings were removed in the evening.

On June 10th he was restless, and complained of pain in the abdomen. The wound was dressed.

On June 11th he had a cough, and expectorated some mucopus. The face was pale. He slept with the mouth open. The tongue was coated, dry, and brownish. There was rapid running pulse; the temperature was 100° F. Crepitation was heard at the bases of both lungs, but was more marked in the right side. The wound was dressed and the tube removed. The wound was dry; there was no discharge, redness, or swelling. The temperature in the evening was 104°. Stimulants, ammonia, and strychnine were given. The patient was unable to cough up sputum.

On June 12th the face was dusky, the skin clammy, and the nares working. He was very restless, throwing his arms about. Stridor was marked. He died at 10 p.m.

Necropsy.—The wound was healed. The region operated upon was dissected, and everything found perfectly healthy. The sympathetic, the phrenic nerve, and the pneumogastric and its laryngeal branches were quite sound. The trachea, compressed laterally, had not resumed its normal shape. There was great congestion of the lungs, some oedema, and commencing hepatisation of both bases, the right lung more affected than the left.

IV.—PEDUNCULATED SEBACEOUS TUMOURS OF THE SCROTUM.
—J. M., aged 23, married, a collier, was admitted to Cardiff Infirmary, August 16th, 1893. Four years ago he had first noticed small hanging tumours in scrotum. Several similar

growths appeared soon after, and increased slowly but steadily in size. On August 25th these tumours were removed under the usual antiseptic precautions. There were three sub-

sequent dressings, and the patient was discharged cured on September 13th.

V.—HYPERTROPHY OF LEFT BREAST.

A. C., aged 31, single, a housekeeper, was admitted to Carcott Infirmary on April 24th, 1888, with enlargement of the left breast, as shown in the accompanying illustration.

It had taken between eight and nine years to grow to the size shown. The breast was generally enlarged, the nipple was normal and freely movable. The skin over the gland was normal and freely movable. The vertical measurement over the tumour was 14 inches, and the horizontal 17 inches. The base measured 27 inches in circumference. There was no pain.

On April 25th, under ether, I removed the breast by an elliptical incision under strict antiseptic precautions. The hemorrhage was comparatively slight and chiefly venous. The breast weighed 7lb. 1 oz. On April 26th the temperature went up to 102° F. The patient was up for a few hours on May 1st, when all fourteen sutures were removed, and nearly the whole line of incision healed. The patient was discharged well on May 23rd.

VI.—SO-CALLED PERFORATING TUMOUR OF THE DURA MATER.

V. M., aged 4 years 8 months, was seen on December 2nd, 1889. Two months earlier, when the child rose one morning, the right ear was seen to be protruding, and on examination a swelling about the size of a hazel nut was seen behind it, smooth, uniformly hard, not painful, and the skin over it was unchanged in colour. The swelling gradually enlarged in all directions. A fortnight later a doctor saw it, said it was a "gathering," and ordered linseed poultice, which treatment was continued for four weeks. It was lanced a week ago, but only blood came out.

When the child came under treatment there was a soft, semi-fluctuating swelling, measuring 5½ inches horizontally and 4½ vertically, and there was right facial paralysis. There was marked optic neuritis on the right side, and commencing neuritis on the left side.

The child lingered on, losing much flesh, and the tumour increasing to such an enormous size as to resemble a second head. She died after several weeks.

Necropsy. (Notes by Dr. D. R. Paterson). Surface of tumour ulcerated and discharging at several points. Seat of

external ear could not be made out. The mass extended into the neck and the glands; these were enlarged. On removing the skull cap a flattened mass of tumour was seen, exerting considerable pressure on the parts about the lower end of the Sylvian fissure and fissure of Rolando. More posteriorly an offshoot of the tumour had penetrated into the

temporo-sphenoidal lobe, and there expanded into a pear-shaped mass. Many parts of the petrous bone retained their consistence of form; they were not absorbed entirely by the tumour mass; only at certain points were ingrowths sent into the brain. The whole tumour was soft and almost brain-like in consistence.

VII.—ANOTHER CASE IN AN OLD MAN.

T. H., aged 75, hawker, was first seen on March 1st, 1890, complaining of nothing definite but suffering from general weakness. He had had a "stroke" eighteen months before on the right side, but recovered; no trace of such an attack was left. On the left side of the head, in front of the parietal region, was a soft, immovable swelling, the size of a hen's egg, which gradually increased to the size of a large orange. It never troubled him, and there was no pain. He was a feeble old man, and seemed to sink gradually, dying on October 19th, 1890. A slight cough troubled him. He was conscious to the last.

Necropsy. (Notes by Dr. D. R. Paterson). On reflecting scalp, the tumour was found to be soft and friable, involving the bone of the skull, which was entirely absorbed, the hard edges of the bone being felt at the margin of the tumour. On removing the skull cap the tumour was found to go through the skull, forming in all a mass about the size of a large orange. It affected chiefly the upper part of the left parietal bone, the adjoining part of the left frontal bone being likewise involved, and extended over the middle line on the vertex. The tumour exerted considerable pressure on the brain, flattening to a large extent the convolutions of the frontal and parietal lobes on the left side. There were no adhesions between the dura mater and the brain. On section the tumour was soft, and had a marbled appearance: sampling of juice showed small, round, and spindle cells under the microscope. On the seventh left rib, in front of the angle, was a small tumour about the size of a walnut, growing from the rib, which was almost absorbed at this point. Microscopically it was similar to the one on the skull.

VIII.—CASE OF FIBRO-ADENOMA OF BREAST.

M. H., aged 50, was first seen in March, 1891. She was suffering from a hard, irregular, freely movable tumour, the size of a goose's egg, in the upper half of the right breast. It had been first noticed in June, 1891, when it was the size of a small nut. I advised removal, which was declined. I

saw her again in September, when slight increase in the size of the tumour was to be noted. She had been trying Count Mattei's remedies, without any effect, of course. In September, 1891, she came to me again expressing a wish for an operation. She had been for nine months under a quack living near Birmingham, who had undertaken to cure her without operation, and had, she said, "nearly killed her."

On September 18th, under chloroform, with all antiseptic precautions, I performed what is called Thomas's operation, by making an incision along the curved groove below the breast, and shelling out the tumour. The drainage tube was removed on September 20th, and the stitches of silkworm gut on September 20th. There were three dressings, and the patient was up on September 30th. The temperature was normal throughout, except on the evening of the tenth day,

when it went up to 100° F. The illustration shows the appearance of the wound on October 6th.

IX. CASE OF ALOPECIA AREATA.

H. R., aged 33, a tailor, was seen on June 13th, 1892. There were several bald patches at the back of the head, which had come on during the previous nine months. He was ordered an ointment of the yellow oxide of mercury (gr. iv to an ounce of vaseline), which he continued to use till the middle of September. The hair commenced to grow again, being at first quite white and very fine. When seen in November, 1894, the hair was black, and there was no remnant of the disease left.

I am indebted to Dr. Morland, House-Surgeon Cardiff Infirmary, and Dr. J. D. Williams, Resident Medical Officer, Cardiff Union Hospital, for assistance in preparing some of these notes.

TREATMENT OF FUNCTIONAL CURVATURES OF THE SPINE BY GYMNASTICS.

By CHARLES ROBERTS, F.R.C.S.

Ours sympathy with Mr. Christopher Heath's efforts to rescue the treatment of lateral curvatures of the spine from the instrumentalists must not be allowed to lead us into the opposite fault of putting too great trust in the gymnasts. A knowledge of the various forms of gymnastics and considerable discrimination in their application is essential. There is no pathological relation between angular curvature due to caries of the vertebrae and its constitutional effects and the functional accommodation of the elastic spinal column to faulty positions and habits of the body, to unequal length of the lower limbs, or to imperfect or irregular action of a few or many of the spinal groups of muscles. The one should be called organic curvature, or, indeed, organic disease, while the others should be called functional curvatures of the spine. If we once get the functional nature of lateral curvatures impressed on our minds, we shall see the uselessness of the instrumental and the recumbent treatment necessary in

organic disease, and we shall set about removing the causes and assisting Nature to restore the spinal column to its normal condition.

Functional curvatures of the spine are—in relation to the conditions which accompany them—healthy and normal. If one leg is shorter than the other there must be a curvature of the spine to a corresponding degree to keep the body erect. This is a cause, but not in my experience so common a cause as Mr. Heath has found it. The spine in young girls is very flexible, and placing a book under one foot will obliterate some lateral curvatures which are not due to unequal length of the two legs. Unless there is a measurable difference between the two legs the curvatures due to this cause need not be meddled with, and when the difference of the two legs is considerable all that is necessary is to alter the soles and heels of the shoes. Without the adjustment of the length of the legs, gymnastics will be injurious as tending to confirm a functional curvature of the spine on an unequal base. Gymnastics are not a remedy for this form of curvature, they serve only to improve the general health.

Next we have a series of curvatures caused by faulty positions in school owing to the left hand and arm being employed to support the body, and the right arm left free to write, draw, hold books, etc. Of the same kind are the curvatures produced by playing active games in which the right hand, arm, and leg are chiefly used. In this class of cases we have a functional accommodation of the spine to balance the body, and in addition, an unequal development of the muscles of the two sides of the body, those of the right side being stronger than those of the left. These are the most troublesome forms of spinal curvature, as correcting the position of the body does not correct the curvature of the spine, the faulty curves being fixed and retained by the unequally balanced muscles. At first sight there does not appear to be any reason why girls should be more liable to spinal curvatures than boys; but girls are excessively right handed, much more so than boys, and this has much to do with initiating, if not actually causing, lateral curvature in girls. It is just because there is this disproportionate muscular development of the lateral halves of the body that gymnastics have to be employed with great caution.

To hand over these cases to the ordinary teacher of gymnastics is not to cure them but to make them worse, because the muscles on the stronger side, being better nourished, grow stronger more rapidly than those on the weaker side. In prescribing physical exercises for this class of cases the immediate needs of the weaker half of the body must be provided for, together with the avoidance of the faulty positions, until the curvatures have been corrected, when general gymnastic exercises may be adopted. Cases of this kind sometimes recover by the use of instruments or the recumbent position, because the faulty positions are forcibly corrected, and muscular action is restrained until both sides of the body become equally impoverished, and a fresh start is made on equal grounds. With proper supervision this class of cases is best treated by gymnastics of the simpler sort with dumb-bells and the like, and not by the trapeze and ropes above the ground. The so-called Swedish system has no advantages over the ordinary methods, and it is slower in its results.

The chief indications for the treatment by gymnastics of the lateral and the cervical angular curvature causing round shoulders are to equalise the muscular development of the two lateral halves of the body, and to favour the freest possible mobility of the vertebra in all directions on each other, and trust to a good carriage of body (due to a good all round muscular development) to secure the true erect position of the spinal column. In cases of functional angular curvature, lying in the prone position with the arms tucked under the chest favours its correction, but little is gained by adopting the supine position in any functional form of curvature except as avoiding unfavourable positions of body.

A very large number—probably the majority of the cases of functional spinal curvature—are hysterical, and are mere imitations of conditions which the patient has seen, or heard described, or read about. I have seen growing-out shoulders and spinal curvatures in cases of chorea maintained throughout the disease, and disappear only with the choreic symptoms, notwithstanding the lack of muscular control by such

patients. For these hysterical cases, sea air, sea bathing and swimming, together with games and gymnastic exercises, are the best remedies, combined with general medical treatment.

I have seen what might be described as an epidemic of "spinal complaints" in a girls' school where the discipline was foolishly prudish and constrained, just as one often sees epidemics—epidemic because catching from one to another—of laughing and crying and other hysterical outbreaks in the wards of a hospital.

NOTES ON THE ETIOLOGY OF GOITRE.

By H. C. L. MORRIS, M.D. Bux., L.R.C.P., M.R.C.S.,
Hambledon.

During two and a half years' residence in Hambledon, Buckinghamshire, I have seen over 50 cases of goitre in my practice, a strikingly large number out of a population of about 2,000; and I have little doubt that there are many more cases that have not come under my observations. The district is situated on and at the foot of the southernmost spur of the Chiltern Hills. The soil is excessively chalky, and, with a few exceptions, the water supply is obtained from deep wells sunk into the chalk. When the springs are low the water is drawn up and even consumed while still milky in colour, for the poor take little trouble to boil or let it settle. I have met with no cases from the tops of the hills, where spring water is unobtainable and the people drink stored rain water.

Of my 55 cases, all were water drinkers, only 4 being males, and the ages ranged from 4 to 76. There seems to me to be little doubt that the presence of calcium and magnesium carbonates in the water is the sole cause of the disease in my cases. When the springs are high the water, tested by Clark's soap test, represents about 30 in 100,000 of total hard matter, but when the springs are low the water is turbid, owing to the buckets disturbing the bottom of the wells.

The following instances are a little remarkable.

A girl, aged 24, who is in service in London, invariably gets an enlargement of the thyroid about a week after she comes home, the enlargement disappearing shortly after her return to her situation.

In another case a family came to reside in this district, having previously lived on a clayey soil. Within six months three out of four children, aged 5, 7, and 8 years, presented thyroid enlargements. There was a little difficulty at first about these children, for I found that their water supply came from a rain water tank. I discovered, however, on making inquiries that the water they drank at school came from a chalk well, and was occasionally turbid. The fourth child, who did not attend school, showed no signs of the disease.

In several other instances new-comers have developed goitre shortly after settling in the neighbourhood.

I feel certain that heredity had nothing to do with the etiology of my cases, for in only one instance was there the slightest suspicion of it. Nor has intermarriage been a factor, for the one village in which the inhabitants have largely intermarried is, if anything, clearer of the disease than those round about it.

The amount of iron in the water is so infinitesimal that I think it can be left out of consideration. That goitre may be produced by other causes in other places I think probable, but that it is produced in this neighbourhood solely by the carbonates of lime and magnesia in the drinking water I feel convinced.

Professor Hanisch, of Prague, has been appointed to the chair of Physiology in the University of Leipzig, vacant by the death of Professor Karl Ludwig.

The annual festival of the Order of the Hospital of St. John of Jerusalem in England, was held on June 24th. After a religious service in St. John's Church, Clerkenwell, which has been reserved, the original crypt of the old church of the Priory of the Order being preserved, the general assembly was held in the Charterhouse under the presidency of the Earl of Lathom.

MEMORANDA:

MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, Etc.

A CASE OF HYPERPYREXIA FOLLOWING INFLUENZA.

The following case seems worthy of record both as regards the rarity of the complication in influenza, and also as being one of the highest temperatures on record in a non hysterical patient. Dr. Bryant, in a collection of 100 cases of hyperpyrexia published in the *Guy's Hospital Reports* for 1894, only quotes one higher temperature apart from pure hysteria, and that was in a hysterical patient suffering from phthisis, in which case the temperature rose to 125°.

A. W., aged 31, married, a publican, had been treated for intemperance. He was not of a hysterical type, and had generally enjoyed good health. From March 26th to April 1st he was laid up with an attack of epidemic influenza similar to the present one except that his temperature never gave rise to any anxiety. The course run by the disease was quite normal. The profuse sweating with its accompanying rash of sudamina was a marked symptom. The recovery from this attack was complete.

On April 15th he complained of feeling unwell, and was seen in the afternoon, when he had a temperature of 102.2°. The pulse was full, 90. He was sent to bed and put on fluid diet, and ordered a mixture containing liquor ammoniac acetatis. As in the previous attack, there was severe sweating, which produced the most marked rash of sudamina and miliaria that we had ever seen. The next day he was more comfortable, the temperature 101.4°, pulse 90. On April 17th he was about the same, the temperature was 102°, on April 18th 101°, and on April 19th 101°. On April 20th he was seen about 3 P.M., the temperature was 103°, the pulse 104; he was chatting perfectly rationally, and apparently in no different condition from what he had presented during the last few days, except that the sweating had somewhat diminished. About 6 P.M. he became suddenly violent, requiring three people to hold him in bed. When seen a few minutes later he was quite unconscious, breathing stertorously; there was no corneal reflex; the pulse was extremely small, about 120; and the temperature was 110.2° (twice taken) in the axilla. Ice was placed in each axilla, and the trunk and arms rubbed with it, but this was of no avail, and he died within a quarter of an hour of being seen.

He had never complained of pains in his joints, nor had he suffered from severe headaches; the lungs were quite free from physical signs on the afternoon of his death.

Dr. Rodman subsequently learnt that after his visit at 3 P.M. on the day of his death the patient had expressed to his wife grave apprehensions of impending evil from his feverishness, from which he could not be dissuaded. He laid great stress upon the fact of his having heard Mr. Rodman say as he went down stairs that his temperature was 103°, and higher than during the previous days.

The case was one of great interest, as within the space of at the most three hours the temperature had risen upwards of seven degrees, and the history given points to the fact that it was only during the last half hour or so of his life that any symptom due to the existence of hyperpyrexia was noticed.

There were no symptoms to point to any pyæmic condition—for example, ulcerative endocarditis or meningitis.

Post mortem decomposition was exceedingly rapid.

East Sheen, S.W. ARTHUR C. HOVENSON, M.B., B.S. Lond.

CONTROL OF HÆMORRHAGE IN AMPUTATION AT THE SHOULDER JOINT.

In recent numbers of the *British Medical Journal* there have been articles by different surgeons on various methods of controlling hæmorrhage in amputation at the shoulder joint. I should like to mention a method which I adopted in 1891, in a case of spreading bacillary gangrene of the arm. My method, I think, differs in some small degree from those already described. An elastic tourniquet was applied round the axilla and tied over the shoulder and an assistant's

finger placed over the subclavian. As these were considered unreliable, I took the extra precaution mentioned below.

An external skin flap was made first by dissection. A circular amputation was next performed through the middle of the humerus; the brachial artery here was plugged with a clot, and therefore did not require ligaturing. An internal skin flap was now made by dissection. The remaining portion of the humerus was next dissected out and disarticulated. The brachial artery was next dissected out, and followed up to its continuation, the axillary, which was ligatured high up above the base of the skin flaps. The knife was then applied circularly through the muscles at the base of the skin flaps, and the amputation completed.

The patient made an excellent recovery, and I used to see him periodically for two years after the operation. He was a native of India.

The cause of the gangrene was the application of a tight ligature (a common practice among natives) for a compound fracture of both bones of the forearm.

House Surgeon, General Hospital, Singapore, Straits Settlements.

"IS CANCER HEREDITARY?"

I THINK the following cases may, perhaps, go some little way towards strengthening the theory that cancer is hereditary, although they were not, as were those mentioned in Mr. Roger Williams's letter, "homotopic," that is, confined to the same organ in each case.

Mrs. J. came to me some months since, suffering from an enlargement on the left side of the neck. After questioning her, I elicited the following family history: Her grandmother (father's mother) died at the age of 99 with cancer of the tongue; she had nine children, of whom one son died at the age of 83 with cancer of the throat; another son died at 83 of cancer of the face; another son (her father), who is still alive and is aged 83, has suffered for years with tumours of the intestine (these, from the history, I should say are probably of a cancerous nature); one of her brothers has had a tumour in his neck, which was removed.

My patient, Mrs. J., I sent up to one of the London hospitals, where the tumour was found to be in the left portion of the thyroid gland. This was, as was then thought, successfully removed, and proved, on microscopical examination, to be cancer. A few weeks after the operation, however, it developed in the remaining portion of the thyroid, grew rapidly, and extended into the tissues of both sides of the neck. She also had a tumour present in the left iliac fossa, which was probably of the same nature; years ago she suffered from uterine polypi, for which she was in a woman's hospital.

In this family therefore we get the history of the grandmother, two uncles, the father (probably), the patient, and one brother (probably) all suffering with cancer; beside this, it is interesting to note the great ages to which the sufferers lived—the patient, the youngest to succumb to the disease, was 57.

Smith Woodford, Essex.

SUPERFETATION: A "WHITE" CHILD AND A "BLACK" FETUS.

THE following case of "superfotation" may prove of interest to some of the readers of the *BRITISH MEDICAL JOURNAL*, from the fact of its rare occurrence and the difference of colour in the fetus and child:

On May 9th I was called to attend a woman in labour. On arriving at the bedside I found that the woman had already been delivered of a female foetus, 8 inches long. The skin was fairly tense, the mouth large and open, the sex distinct, the nails just appearing, and the umbilicus near the pubes; from these conditions I inferred that the foetus was about four months old, the cord being about 18 inches long. The foetus was dark-coloured like the mother, who is an East Indian labourer. The placenta had to be removed. About half an hour after the removal of the placenta I delivered the woman of a fully-formed full-term female infant, which had all the appearance of a "whiteman's child," as it is here called. This was so very noticeable a fact that two or three persons who saw

the infant made a remark to that effect. The placenta was expelled at the same time.

The mother denied any possibility of its being a "whiteman's child," but this is only natural on her part, particularly when there exists such an intense jealousy on the part of the East Indian husbands.

The child is doing very well, and the mother is up and has been attending to her house duties for some time.

REPORTS

MEDICAL & SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

UNIVERSITY COLLEGE HOSPITAL.

TWO CASES OF PERFORATED GASTRIC ULCER TREATED BY OPERATION.

(For the Notes of these Cases we are indebted to Mr. DOUGLAS DREW, F.R.C.S., Surgical Registrar.)

[CASE I.—Under the care of Mr. BILTON POLLARD.]

C. A., aged 18, was brought from her home, about one mile distant, in the hospital ambulance, on the evening of January 22nd, 1895.

She had been anemic for some weeks and had suffered occasional pains in the epigastric region, not increased by taking food, slight vomiting at times, and shortness of breath on exertion. Some months previously she had had a more severe attack of pain accompanied by frequent vomiting. Indigestion had been complained of for about two years. Menstruation had been quite regular. She was fond of vinegar and frequently took it with food.

About 7 p.m. on January 22nd, she was lifting a pail of water, when she was seized with sudden and severe pain in the epigastrium, which radiated round the left side to the back, and was followed by the vomiting of a small amount of brownish material, and frequent retching, with severe shock and rapid distension of the abdomen. Two hours and a-half before she had had tea, consisting of bread and butter with two slices of cake, and no pain followed the meal until the sudden onset at 7 p.m. At the time of admission, about six hours after the accident, the abdomen was extremely distended and abdominal respiratory movement was absent; the percussion note was tympanitic all over, obscuring the liver dulness and extending upwards to the fifth rib in the right nipple line. There was no dulness in the flanks; shock was severe, the face being pale and extremities cold. The pulse was 120, small, regular, and compressible. Respirations 32.

Dr. J. Rose Bradford saw the patient with Mr. Pollard, and concluded that perforation of the stomach had occurred. Operation was at once decided on, and was performed by Mr. Pollard 7½ hours after the onset of the symptoms. Chloroform was administered and an incision in the middle line was made from 1 inch below the ensiform cartilage to 1 inch above the umbilicus. At a later stage of the operation, the incision was extended downwards for 3 inches in order to facilitate the flushing out of the peritoneal cavity. On opening the abdomen, a free escape of gas occurred and the walls collapsed. The anterior surface of the stomach was exposed; it was abnormally red, and scattered over the surface were flakes of lymph. Search was made for a perforation; but a view of the cardiac end could not be obtained on account of some firm adhesions between the organ and the parietal peritoneum. These were divided, and by gently drawing the stomach towards the right a perforation was found situated on the anterior surface 1½ inch from the greater curvature. As the space was rather limited, the wound was extended by a transverse incision to the costal margin. Several branches of the superior epigastric artery lying in the rectus muscle were divided and ligatured; the perforation was thus brought fully into view, and was found to measure ½ by ½ inch; its edges were smooth and thin, and,

as the stomach wall for about 2 inches around was much indurated, it was decided not to excise the edges of the ulcer. The perforation was closed by seven fine silk Lambert sutures inserted with a round sewing needle, and passing $\frac{1}{2}$ inch outside the edge of the ulcer. One suture at each end was placed beyond its limits; as an additional security a second row of seven sutures was inserted after the first row had been tied, so that by further invaginating the wall of the stomach the first row was buried.

The abdominal cavity was very thoroughly cleansed by flushing out with boiled water at 100° F., and by sponging until it was nearly dry. The fluid at first came away very turbid, and collections of semi-digested food were found beneath the liver and in the left flank. Flakes and films of lymph were removed from both surfaces of the liver and from the right flank by the flushing and sponging. The abdominal wound was closed without drainage. The patient bore the operation, which occupied an hour and forty minutes, remarkably well. An enema, consisting of an ounce of brandy with tincture of opium $\frac{1}{2}$ xx, was given with warm water at its completion, and in a few hours the shock passed off. Eight hours after the operation she vomited a quantity of offensive sticky material resembling pus; microscopically it was found to consist of fat globules and debris, with a few pus cells and numerous streptococci.

The vomiting continued at intervals for rather more than twenty-four hours, so a little ice was given. It recurred in the evening of the second and fourth days. Nothing was given by the mouth, except the ice mentioned, until the fourth day, when a teaspoonful of hot water was given every hour. Flatulence was complained of, but no further vomiting occurred. The pulse was 82, the temperature 100° F., and the condition of the patient satisfactory. During the first three days hypodermic injections of morphine were administered on account of pain.

On the fifth day the dressings were changed. The lower part of the wound looked well, and was quite dry, but at the upper end a small quantity of sour-smelling pus was found. The edges of the wound were somewhat red; the stitches were beginning to cut. The abdomen was not distended, and moved with respiration. Daily dressings were resorted to as the suppuration was rather free. The temperature was slightly raised, varying between 97° and 100.2° F.

On the ninth day the deep stitches were removed; the lower half of the wound was completely healed, an abscess had formed in the track of one of the sutures on the left side, so a small drainage tube was inserted after the removal of the stitch.

On the tenth day milk and barley water, a drachm of each, was given hourly instead of the hot water, and nutrient enemata, which had been injected four-hourly from the first day, were continued.

On the twelfth day the superficial sutures were taken out. She was quite free from pain, and no vomiting had occurred after the food, which was therefore increased to half an ounce of milk and barley water hourly.

On the fourteenth day slight vomiting occurred. Food was omitted for a few hours. The discharge from the wound was rapidly decreasing.

On the seventeenth day she was taking three ounces of milk three-hourly, and after this date the diet was cautiously increased until ordinary light food was being taken at the end of a month.

An attack of phlebitis in the calf of the left leg came on towards the end of the third week; this subsided in about ten days.

At the end of a month she was allowed to sit up in bed. The wound was then almost healed. At the time of discharge on the forty-fourth day to her home in the country, the wound was firmly united. She was feeling very well, and gastric symptoms had not returned.

During the first week after the operation the percentage of urea was estimated and found to be as high as 64 per cent. the quantity passed was not measured, but was probably small on account of the limited supply of fluid. About the middle of April the patient reported herself as quite well.

REMARKS BY MR. POLLARD.—This case is an instance of the striking success which may attend the surgical treatment of perforated gastric ulcer. It was in several respects a

favourable one for operation. The patient was a nursemaid in a doctor's house, and to this fact may be attributed the rapidity with which the seriousness of the accident was recognised and the care with which the patient was removed to the hospital. The operation was commenced $7\frac{1}{2}$ hours after the perforation occurred. The time at which the perforation happened was fortunate. It took place $2\frac{1}{2}$ hours after the smallest meal of the day—tea—which did not include any indigestible food. The diagnosis of the condition was simple. It rested on the sudden onset and severity of the symptoms, the situation of the pain, and the presence of free gas in the peritoneal cavity. The operation was unattended with difficulty after a transverse cut through the upper part of the left rectus muscle had been added to the original median incision. A good deal of creamy material had escaped from the stomach, but no particles of undigested food were recognised. The presence of large films of lymph on the surfaces of the liver and in the right flank as early as seven hours and a-half after the occurrence of the perforation was noteworthy. The induration extended so far beyond the perforation that the removal of the diseased tissues would have left a wound which would have been very difficult to close. It is, indeed, doubtful whether in any case it is wise to excise the ulcer. The perforation was easily inverted, and securely closed by a double row of Lambert's sutures. The only drawback in the case was the occurrence of an abscess in the track of one of the stitches uniting the transverse portion of the wound. It is probable that this portion of the wound was infected by the material which was washed out of the abdomen. There was at no time after the operation any evidence of intraperitoneal suppuration. The abscess in the abdominal wall was very septic, and to the general septic infection from this source, acting in conjunction with intense anemia, the thrombosis of some superficial veins in the leg must be attributed. The rapidity with which the patient recovered from her anemia was remarkable. Within three weeks of the operation she had a good colour, and looked better than her friends had known her to do for months previously.

REPORTS OF SOCIETIES.

BRITISH GYNÆCOLOGICAL SOCIETY.

CLEMENT GODSON, M.D., President, in the Chair.

Thursday, June 15th, 1895.

SPECIMENS.

DR. MACPHERSON LAWRIE showed: (1) Removal of Suppurating Ovarian Tumour, with Purulent Peritonitis and Adhesions; (2) Fibroma of the Uterus, removed by Enucleation; (3) Total Extirpation of the Uterus and Ovaries for Prolapse, in a woman, aged 30, who had strained herself in lifting. An ineffective attempt was made to retain the uterus in position by pessaries; the uterus, together with the appendages, was removed. Later she suffered from rectocele, which was treated by a plastic operation. She was now well. The PRESIDENT questioned the advisability of removing the uterus and ovaries for prolapse in a woman of 30. Dr. ROBERTS took exception both to the removal of the uterus and to the removal of the ovaries.—MR. CHRISTOPHER MARTIN showed two Uteri, removed by total extirpation, after removal of the appendages, in each case two years previously. In the first case the appendages were removed on account of double prostatic hypertrophy. Menstruation continued very profusely. After other methods of stopping the hæmorrhage had failed, vaginal hysterectomy was performed. It was found that a piece of an ovary had been left behind. The patient made a good recovery, and had had no more hæmorrhage. In the second case the first operation was a double ovariectomy for cystic disease. Menstruation continued, not profuse, but with excessive pain. As a last resource he performed total extirpation of the uterus by abdominal section. It was found that part of the Fallopian tubes had been left behind. There was also a myoma in the anterior uterine wall. Mr. Martin attributed the persistence of menstruation to the fact that owing to incomplete removal of the broad ligament the nerve had been left

intact. Dr. LEITH NAPIER said that the thickness of the uterine wall in the second case was suggestive of fibrosis, which often caused a continuance of hæmorrhage, even after removal of the ovaries. Mr. TAYLOR (Birmingham) said that these were examples of a class of case in which hysterectomy had an important place, contrasting in this respect with Dr. Lawrie's case, in which the procedure was open to serious criticism. When menstruation continued with severe pain or hæmorrhage, after removal of the appendages, hysterectomy was often the only cure.—Mr. TENISON COLLINS (Cardiff) showed an impacted Ovarian Cyst which, in all its signs and symptoms, simulated a myoma of the Uterus.

SOME DIFFICULTIES IN THE USE OF THE CURETTE.

Dr. FANCOURT BARNES read this paper. Curetting, he said, though a simple procedure, was not devoid of risk. The first step was dilatation, which should be carried sufficiently to admit the passage of the index finger. There were two methods of dilatation. The rapid method was done under an anæsthetic by means of Hegar's or other dilators. At the best it was a somewhat rough procedure, involving tearing and bruising of the cervix; he therefore generally preferred the gradual method. Gradual dilatation was obtained by tents, which secured a greater amount of dilatation with greater safety. Laminaria tents were to be preferred, because the salts with which they were impregnated rendered them aseptic and even antiseptic. Sponge tents were to be condemned. He used tents 4 inches long. Under an anæsthetic the curetting was next proceeded with; often the finger nail was sufficient and satisfactory; in other cases a curette had to be used. The risks attendant on curetting were perforation of the uterus and hæmorrhage at the time of operation; and, later, atresia of the canal and pelvic inflammation. The two principal conditions calling for the use of the curette were chronic endometritis and retained products of conception. Cases were related illustrating these conditions. In conclusion, the following questions were submitted for discussion: 1. What are the symptoms which point to the clear necessity of curetting the uterus? 2. Which is the safest and most natural method of dilating the uterus? 3. Should the curette be used in cancer of the uterus, more especially when the growth is at the fundus? 4. Is it advisable to resort to the use of the curette as a means of making a diagnosis? 5. Is it possible to establish a satisfactory system of drainage of the uterine cavity after curetting?

The PRESIDENT said that as curetting was a popular operation, it was advisable that the method of its performance and the selection of cases should be discussed. Whilst many operations rose for a time into prominence and then lapsed, he thought it unlikely that this one would fall into disuse, because the resulting benefit was often strikingly evident.

Dr. MACPHERSON LAWRIE had done many curettings, but felt a certain anxiety about every case; yet no operation gave more satisfactory results. He used laminaria tents and a sharp curette; the cavity was then flushed with boiled water. Complete rest was required for some days after.

Surgeon-General HARVEY had operated in India both on Europeans and on natives, and had not found an anæsthetic necessary. He agreed with Dr. Barnes that sponge tents should be abolished. Even laminaria tents were not always satisfactory, for sometimes they expanded in an hour-glass fashion, and their extraction was then difficult.

Professor JAPP SINCLAIR had also not found chloroform necessary; he gave a hypodermic injection of morphine an hour before the operation, and an alcoholic stimulant half an hour before. He had never seen any bad symptoms follow curetting, nor need there be any if care was used. Tents formed the best dilators; it did not matter much how long they were left in, especially when the uterus was tough. He thought it was seldom necessary to introduce a finger, but when desired Hegar's dilators could be used up to No. 12. The curette had an important use for diagnosis of cancer of the body of the uterus; whilst in cases of suspected cancer of the cervix, if a sharp curette were drawn across the diseased part, if it brought away tissue the disease was cancer; if not, and there was only a little bleeding, they had to deal with an erosion. He believed this sign to be pathognomonic.

Mr. GREG SMITH doubted the value of the sign given to them by Professor Sinclair in his last remarks. In his experi-

ence a sharp curette applied to an erosion would certainly bring away tissue. He usually neither dilated nor gave an anæsthetic; but pulling the uterine canal straight by means of a volsella on the posterior lip, any moderate sized curette could be introduced.

Mr. C. MARTIN said there was one condition which had not been referred to, but which was capable of causing serious trouble after curetting, namely, mild disease of the appendages. In America curetting was done for this very condition, but he did not think it safe. A careful examination of the appendages should, therefore, always be made before curetting. In Birmingham they always gave an anæsthetic and used metallic dilators; a sharp curette was used, after which the cavity was swabbed out with iodised phenol, and packed with iodoform gauze.

The discussion was adjourned.

REVIEWS.

THE GALENICAL PREPARATIONS OF THE "BRITISH PHARMACOPŒIA." A Handbook for Medical and Pharmaceutical Students. By C. O. HAWTHORNE, M.B., Lecturer on Materia Medica and Therapeutics, Queen Margaret College, University of Glasgow. London: J. and A. Churchill. 1895. (Demy 8vo, pp. 126. 4s. 6d.)

THE ultimate attainment of a desirable uniformity in medical practice may be regarded as having been one of the main objects with which the amalgamation of the three different *Pharmacopœias* of London, Edinburgh, and Dublin was undertaken, and consequently the precise definition of the substances which the physician prescribes is one of the most important conditions to be secured in regard to both medicine and pharmacy. The *British Pharmacopœia* has undoubtedly helped to promote progress in that direction, and from that point of view it requires to be carefully studied by medical men as well as pharmacists. While for the latter the *Pharmacopœia* is the standard and rule for the preparation of medicines, its utility would be diminished if medical practice were not generally regulated by regard for its definitions. It is to secure such a result that Dr. HAWTHORNE has for some years past delivered a course of lectures at Glasgow, and has now given, in book form, the facts forming the basis of his lectures.

The volume is chiefly intended for the use of medical students, and is therefore adapted to their special requirements when engaged in the application and administration of medicines as remedies. It is very properly considered unnecessary that medical students should burden their memories with details as to the preparation of medicines, or that they should be expected to have more than a general acquaintance with the materials and the processes by which medicines are prepared. The knowledge and technical skill appertaining to the selection of drugs and the manufacture of medicinal preparations fall within the province of the pharmacist, and the more the standards of the national *Pharmacopœia* become efficient and recognised, the more thorough will be the division of labour in regard to the preparation and use of medicines. But even with these limitations it is no light task for the medical student to acquire that thorough knowledge of official medicines which is essential for the practice of his art, and it is to facilitate the study of the subject from the therapeutical side that the work now published by Dr. Hawthorne has been prepared. It contains a careful classification of the facts to be borne in mind in prescribing, elucidated by explanation of principles and by the introduction of elementary therapeutical facts which will materially assist medical students in this part of their work, and prove of practical value to them.

After some brief introductory definitions and a general description of the processes by which Galenical preparations are made, the author proceeds to deal with these preparations in thirteen groups, commencing with infusions, decoctions, and waters as the first group, and ending with ointments and oleates. Within the space of about a hundred pages the formula, composition, strength, and dose of the preparation belonging to these several classes are described,

well as the principles involved in their manufacture, and useful hints are given as to their use as remedies in medical practice. The pharmaceutical information requisite for medical practitioners is thus furnished in a very convenient form, which is calculated to make this small volume a most useful and desirable source of instruction for students.

Brief appendices are added, describing the regulations of the Pharmacy Act relating to the sale and dispensing of poisons; the British and metric systems of weights and measures and their relations to each other; the chemical nature of alkaloids, glucosides, and other proximate principles of drugs. There is also a full and well-arranged index. The publication of this work—written with a very thorough knowledge of the subject it treats of—is decidedly opportune, and it may be expected to contribute very largely to making the official preparations of the *British Pharmacopœia* better known among general practitioners in the future and thus to give effect to the intention that the national medicine book should become the one uniform standard and guide, whereby the nature and composition of substances used in medicine may be ascertained and determined.

TEXTBOOK OF DISEASES OF THE KIDNEYS AND URINARY ORGANS.

By Professor Dr. FÜRBRINGER. In two volumes. Vol. I. Translated by W. H. GILBERT, M.D. With a Preface by Sir T. GRAINGER STUART. London: H. K. Lewis. 1895. (Demy 8vo, pp. 204. 7s. 6d.)

THE first volume of the translation of Professor FÜRBRINGER'S work is limited to the strictly medical, whereas the second volume deals with the more surgical, part. The first volume is divided into two sections, the first of which is given to general remarks on albuminuria, hæmaturia, hæmoglobinuria, renal colic, dropsy, and uræmia. In the second section, the subject is dealt with under the following headings: (1) Circulatory disturbances; (2) nephritis; (3) affections of the kidneys leading to suppuration. Under the head of Circulatory Disturbances, the following affections are considered: (a) The cholera kidney; (b) renal affections in pregnancy; (c) the engorged kidney; and (d) the hæmorrhagic infarct. Under the inflammatory affections of the kidney, the ever recurring difficulties of classification are to be found. To those with any *post-mortem* experience, the utterly unsatisfactory classification of the various forms of nephritis is only too obvious, and this fact is emphasised in these pages on several occasions. Diffused nephritis is here divided into (a) acute; (b) chronic form without atrophy or marked amyloid degeneration; (c) chronic form with decided atrophy and general renal sclerosis; completely contracted kidney; and (d) amyloid kidney. It is certainly open to some objection to classify the lardaceous kidney (as usually understood) as well as at least some forms of the contracted kidney under inflammatory affections. The author would enlarge the class of amyloid kidney at the expense of chronic nephritis, as some degree of lardaceous disease with or without other changes appears in his experience not to be uncommon. Physiological albuminuria, the so-called febrile albuminuria, and the etiology of acute nephritis are especially satisfactorily dealt with. This work will be read with much interest and profit, more perhaps by those already acquainted with the subject rather than by the beginner, as it is somewhat burdened with authorities. The laborious work of translation has mostly been well done, but occasionally the English is somewhat stilted. There can be no advantage in substituting such terms as "climacteric," "purulence," "expectatively," for the well-recognized forms of climacteric, suppuration, expectantly.

PILGRIMAGE A LA MECQUE ET A MEDINE [Pilgrimage to Mecca and Medina]. Par le Dr. SALEM SOLEIMY. Le Caire: Imprimerie Nationale. 1894. (Demy 8vo, pp. 130. 6 50c.)

THIS book is mainly an account of the Mohammedan pilgrimage to Mecca and Medina, written by a medical man occupying an official position under the Egyptian Government, who spent over eight months in the Hedjaz and had ample opportunity of observing what went on. Its pages give the reader a fair idea of a modern pilgrimage carried on with the aid of railways and steamboats. Owing to the very

large number of pilgrims who by these means can be rapidly concentrated upon a small area, a much more perfect system of sanitation becomes requisite than was the case in days of caravans and small sailing boats, when travel was so exhausting that the ranks of the great army of pilgrims were thinned before arrival, and so slow that the survivors had become inured to hardship before they reached the goal of their desires.

Now great shiploads of untrained travellers are dumped upon the shores of the Hedjaz in the midst of a sanitation suited only to the Middle Ages. The author describes the method adopted for disposing of the contents of the latrines by burying them in pits dug in the sandy soil, through which the fluid slowly but surely finds its way into the neighbouring cisterns. He also points out that although the Turkish Government gave a considerable sum for the construction of an aqueduct by which pure water could be brought to Djeddah, and although it was actually made, yet at the instigation of the rich and influential proprietors of the cisterns the aqueduct was either destroyed or allowed to get out of repair, so that the pilgrims still have to buy the cistern water, which is of the vilest description.

This is but an example of the way the unfortunate pilgrims are dealt with.

Little information is given regarding the sacred well of Zemzem in Mecca, but it is incidentally mentioned that, as this well is popularly considered to open into Paradise, many pilgrims did not hesitate in former times to commit suicide therein. The fact that their bodies were never recovered added no doubt to the strength of the superstition. At the same time it did not add to the purity of the water, and it is satisfactory to know that the Turkish Government has now placed a grating to prevent any further use of this short cut to Paradise.

A ghastly picture is drawn of the sacrifices at Mounah, where nearly 300,000 sheep are slaughtered, and of the evils which result from so great a mass of decomposing material. The author asks that the carcasses should be burned. He also suggests that more care should be taken as to excrement disposal, and the provision of purer water; that Yambo, the point of departure on returning by sea, should be provided with a telegraph, so that warning might be given to Egypt of any outbreak of disease among returning pilgrims; and that a railway should be constructed from Djeddah to Mecca, from Mecca to Medina, and from Medina to Yambo, so that the whole tour could be done by rail. He also makes the suggestion that as cholera reaches Mecca from the south it should be arranged throughout the Mohammedan world that pilgrimages to Mecca from the north and from the south should take place only on alternate years, so that the two sets of pilgrims should never touch or intermingle.

A CONTRIBUTION TO THE ETIOLOGY OF CHOLERA. By M. W.

M. HAPPEINE and W. J. SIMPSON, M.D.

THIS pamphlet, which is a reprint from the *Indian Medical Gazette*, March, 1895, is an attempt to show that in Nature there are no water comma bacilli except those connected with cholera. The authors have made an exhaustive examination of the tank and other waters of Calcutta, and arrive at the conclusion that (within the limits of error of experiment) those tanks near which cholera has been known to exist during the past year contain comma, while others in the vicinity of which no cholera has occurred are free from that organism. This reasoning, as far as it goes, can never result in more than presumptive evidence, and the authors' conclusions must therefore only be accepted in this light. The authors do not tell us what measures were adopted to confirm the diagnosis of the comma as veritable cholera forms, and this, in view of the well-known results of modern investigations, according to which several well-defined species of non-choleric comma have been described in water, and of the above criticism, might in the hands of anyone not knowing as we do the authority with which the authors can speak, seriously detract from the value of the paper. But we have no doubt that every precaution was taken, and the piece of work—which must have been laborious in the extreme—may be taken as affording additional argument to those who hold similar views on the etiology of cholera to those advanced by

the authors, though we might with the same justification consider as effect what the authors look upon as cause, and vice versa.

NOTES ON BOOKS.

Disinfection and Disinfectants: Practical Directions in Accordance with the most recent Information on Disinfectants. Compiled for the National Health Society by JOHN GAY, M.R.C.S., L.R.O.P., D.P.H. (London: Allman and Son, Limited, 1895. 1d.)—The leaflet on disinfectants issued by the National Health Society has been revised and brought up to date by Mr. Gay, who gives in some dozen pages a brief account of such disinfectants as are of real practical value, with directions for their use in various circumstances. The information given is set out in a clear and condensed form. Exception may be taken to the inclusion of permanganate of potash among "the most reliable germicides which will kill the spores of bacteria," the question of time being here one of importance, and a 5 per cent. solution (the strength recommended) requiring twenty-four hours to destroy anthrax spores. Again, the advantages of steam over dry-heat forms of disinfecting apparatus are not sufficiently insisted upon. The pamphlet contains much information in a small space, and should prove a useful addition to the series of publications issued by the Society.

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

A URETHRAL KNIFE.

DR. JAMES MACMURR (Finsbury Pavement, E.C.) has designed a urethral knife, illustrated in the accompanying woodcut, for the division of strictures of the meatus and those not far down the urethra. The chief point in its construction is that it only cuts at B. At A it is blunt, and thus slides on the mucous membrane and severs only the obstruction. The angle C also is blunt to render withdrawal free from risk of injuring the healthy part of the urethra. If used for deeper strictures the handle ought to be elevated on withdrawal after the narrowing is cut. To cut flush with the mucous membrane and to a size not exceeding that of the urethra anterior to the stricture is the object aimed at. The site of the stricture should first be ascertained with a bulbous instrument, and the distance to which the knife should be introduced should be measured on it. The knife is made by Messrs. Arnold and Sons of West Smithfield, E.C.

CELLULOID VAGINAL DOUCHE.

MR. ROBERT H. RAINS, M.R.C.S. (Caledonian Road, N.) has designed a vaginal douche made of celluloid, for which he claims certain advantages. The vaginal tube is large enough to open out the vaginal folds, and being perforated, as shown in the drawing, renders it easier to wash out the vagina thoroughly than by other patterns. The material of which it is made is unbreakable, and being transparent contributes to ensure cleanliness. It is provided with an inflatable india-rubber cushion to occlude the vaginal outlet, and is self-retaining owing to the expanded extremity. It can thus be used by the patient herself, and being provided with a large wastepipe the risk of wetting the bed is obviated, and a drawsheet is unnecessary. Any ordinary india-rubber syringe can be used for supplying the fluid for injection, as is shown in the drawing. If it be

desired to flush out the vagina this can be effected by pinching the wastepipe while the bulb of the syringe is compressed

two or three times; when the wastepipe is liberated the injected fluid, and with it any blood or discharge, is forcibly expelled through the numerous apertures in the vaginal tube and into the wastepipe. The apparatus takes to pieces easily for cleaning, and can be supplied with a uterine tube. The appliance is made by Messrs. Arnold and Son, of West Smithfield, E.C., and has been protected.

IMPROVED TONSIL GUILLOTINE.

MR. LEONARD ROGER, M.B. Cantab., clinical assistant in the Throat Department of Guy's Hospital, writes that the accompanying woodcut shows a slight addition to Mackenzie's guillotine. Hitherto he has frequently found that the blade, when withdrawn and ready for use, presents on each side a sharp edge extending from a quarter to nearly an inch in length. Messrs. Down Brothers have extended the slot in

which the blade works, so that when the latter is withdrawn to its fullest extent it is still guarded. His excuse for venturing to add to such a well-known and generally used instrument is that when dressers first commence to remove tonsils under an anæsthetic, he has not infrequently seen the lips and tongue cut by unguarded sides of the blade. A comparison of an ordinary guillotine with the woodcut will make the addition more obvious.

On Tuesday, June 11th, a complimentary dinner was given at the Regent Hotel, Leamington, by the members of the medical profession in Leamington and the neighbourhood, to Dr. F. H. Haynes, upon the occasion of his election as a Fellow of the Royal College of Physicians of London.

WATERBORNE TYPHOID: A HISTORIC SUMMARY OF LOCAL OUTBREAKS IN GREAT BRITAIN AND IRELAND, 1858-1893.

*A Report Prepared for the Parliamentary Bills Committee
of the British Medical Association.*

By ERNEST HART, D.C.L.,
Chairman of the Committee.

(Continued from page 148.)

CANALS AS WATER SUPPLIES.

In his report on the river Trent, to which I have already had occasion to advert at some length, Dr. Bruce Low gives prominence to the use of canal water in relation to typhoid causation. This is especially the case in respect of the villages of Misterton and Wakeringham, in the Gainsborough rural sanitary district (No. 174). In view of the fact that canal water was still being used here in 1893, I think I ought to show what were some of the constituents of the supply which the villagers were consuming. Accordingly I quote a short passage from Dr. Low's report:

"The Chesterfield Canal, which passes through the parishes of Misterton and Wakeringham, joins the Trent at West Stockwith, where are a lock and canal basin. Inland beyond Misterton, and to the south-west, the most important place on the canal is Retford, whence cargoes of nightsoil are brought in barges for disposal on the celery-growing land in and round about Misterton parish. From the south-east cargoes of nightsoil are also brought into the Chesterfield Canal from Gainsborough, and from Lincoln *via* the Foss Dyke, another canal which joins the Trent at Torksey. This nightsoil, along with towns' manure, is unloaded on the banks of the canal in Misterton parish, sometimes close to the village, and some of the filth is usually spilt into the water and on the banks during the process of unloading. The nightsoil before being carted away is heaped up on the bank, a few feet from the water's edge, and eye-witnesses inform me that they have seen the liquid filth exuding from the heap, running directly into the canal. The bilge water remaining in the barges after unloading is pumped out into the canal. The amount of nightsoil manure passing *via* the canal from the river Trent is estimated at from 500 to 600 tons in the year; this does not include that which comes from Retford in the other direction."

This surely is bad enough; but even worse is told by Dr. Low, since he says that this canal water has a "general preference" expressed for it by the villagers as opposed to pump wells. In the same report we are told that the town of Thorne derives its supply of drinking water from a canal fed by the waters of the river Don. True, the supply is subjected to some amount of filtration of a rough character; but the canal itself is the recipient of untold abominations. Dr. Low says: "The canal in question is fed by the waters of the river Don, which itself forms, for some miles above, a part of the navigable waterway. The Don is largely polluted by sewage and other refuse matters in its course through the Sheffield, Rotherham, and Mexborough districts, and other populous places; it is also continually contaminated by the bowel discharges, urine, and slop water of a large floating population. On one occasion, a few years ago, the number of canal boats passing up and down through the Thorne Lock in one week was counted, and the number enumerated amounted to 500. So that 500 boats carrying each four persons would represent 2,000 persons contributing excrement to the canal in the Thorne district at one time or another during the week. Habitual throwing into the canal from barges of all their excrement and slops by boatmen was not denied. Towards the Doncaster end of it I myself saw many loads of black sludge being taken out. One look-keeper told me he often saw the carcasses of dead dogs and cats in the canal, and that he had occasionally himself to assist in taking out of the water the decomposing bodies of drowned persons." That canals should be totally prohibited as suppliers of drinking water no one, I take it, will seek to gainsay after reading what is here said.

FILTRATION OF DRINKING WATER.

The importance of the method of filtration adopted in regard of water intended for human consumption need hardly be asserted. And yet it is one which has received far less attention in the past, at least in our country, than should have been given to it. Professor R. Koch has brought out very clearly in his paper of 1893 on Water Filtration and Cholera that it is not the sand of the filter beds that acts as the purifier of the water passed through the filter, but that a layer of mud on the top of the sand, brought there by a deposit from the still unpurified water, is in reality the means of filtering the water. The most important point in connection with efficient filtration is the deposition of this layer of mud, which after formation should not be disturbed until it becomes so thick that it requires removal on account of its impermeability. The layer of sand below this deposit should never be permitted to get under a certain thickness, about 30 cm., and in respect of the filtering mud layer it is essential that the water to be passed should in the first instance be allowed to remain on the sand bed a sufficient time to deposit the mud, the time required to bring about the deposit differing with different waters and the capability to rid themselves of their suspended mineral and vegetable matter. Some river waters, we are told, which are especially rich in clay constituents can deposit a good filtering mud layer in eight or ten hours, whilst others, having vegetable matter in suspension, require at least twenty-four hours for the process; hence the matter of sand filtration is seen to be by no means the simple subject that many have supposed it to be. We are further told that if a filter works satisfactorily there should never be more than 100 germs capable of development in each cubic centimetre of filtered water, and this notwithstanding the number in the unfiltered water, whether 100,000 or only a few hundreds. In the case of very contaminated natural water the germs after filtration should never exceed 100 in a cubic centimetre. A small proportion of the bacteria found in filtered waters have their origin, according to Fraenkel and Pieske, in the natural water; hence the very best filters yet devised cannot rid the waters of all micro-organisms, with the sole exception of the Pasteur filters. Indeed, at the rate of filtration which Professor Koch would allow, he fears that the bacteria of cholera could not be kept back; but whilst sand filtration cannot be held to give absolute protection against danger of infection, "it can give such a protection that in practice we may, under existing circumstances, be satisfied with it." The danger to be feared from the process of cleansing the filter beds is adverted to, and it is shown that even with the most careful manipulation of the plant there will be some disturbance of the filtering area by the inflowing water after the beds have been cleaned. This, however, need be but slight, and danger may be avoided if the proper precaution be taken of permitting the water to rest for the hours requisite to allow of a deposit before the filters are again put into play. Commenting on the cholera outbreak at Nietleben in 1893, Professor Koch states that if proper bacteriological examination had been made of the so-called filtered water prior to the outbreak, such an examination would have sufficed to show that the water passed through the filter beds was not of such a quality as was proper to be sent into the service reservoirs. The object to be aimed at in that case seemed to be to get as much water as possible through the filters, irrespective of the nature of the filtration to which the process treated the water. The fact was not appreciated that the water needed to be allowed to rest for four-and-twenty hours on the sand previous to fresh use of the filter beds. To such ignorance Professor Koch would seem to refer the cholera epidemic outbreak at the asylum there.

This brings me to the further and very important matter of the periodical and frequent examination of water, after filtration. In a bacteriological sense, it is perhaps scarcely necessary to state that in England this question has not received the amount of attention which it merits. Unless I am greatly mistaken, the waters of the individual companies supplying London are only examined (to the extent of a few drops) once a month. But what do we find Professor Koch

¹ In this connection I have thought it well to print in appendix the account which Dr. Klein has given of his "methods of examination of water when searching for the bacillus of typhoid."

saying on the matter? This, namely, that there should be a rule that each filtering basin should when in use be bacteriologically investigated once every day, the basin being so arranged that a sample of the water can be taken immediately after passing the filter, and prior to mixing with the waters from other basins or reaching the storage reservoirs. He does, however, go on to say that if waterworks are so constructed that they give uniformly good results, periods of greatest use of water, of frost, or of danger of epidemics, are alone those in which the strict insistence of a daily examination need be carried out, an examination every three days of the total filtered water being in the meantime sufficient. But the practice of a weekly bacteriological examination at any time is recorded as insufficient. I much fear that the water companies of our country, if judged by this standard, would come out of the ordeal very badly. And again, if the water passing had in our country to stand the test of having a number of germs capable of development in each cubic centimetre below 100, I imagine that the companies would be in equally bad case. If we apply these various desiderata to the case of the Tees water as supplied to consumers, I am afraid that the inability of the Water Commission of 1893 to determine whether the fever in the Tees valley was or was not waterborne is shown to have less justification than ever. Coming to an instance of filtered water which has seemed certainly to have caused typhoid, I would draw attention to the case of the Chester-le-Street outbreaks of the winter and spring, 1892-93 (No. 195), where the incidence of the disease was most emphatically marked on one of two water services in the place. The data given in the appendix sufficiently demonstrate this fact. The inquiry which was made of the prevalences of typhoid for the Local Government Board by Dr. Maclean Wilson is an admirable instance of the reports issued by the Medical Department of that Board, and I feel that I may with advantage to this paper quote from the document as to the methods of filtration found to be in vogue when Dr. Wilson visited the district. The length of the extract is only the measure of the importance of the subject dealt with.

"The Chester-le-Street Company draws its supply from the Stanley Burn, about two miles above the village. At the intake there is a weir to direct the water into the pipes, the open ends of the pipes being protected by a double wire screen to keep out leaves and other floating bodies. But at the time of my visit these screens were so arranged that the water did not require to pass through them to enter the pipes. A few yards lower down these intake pipes deliver into a settling tank about 3 feet square, and from this the water flows into the main, which is said to be covered by a rose. The main conveys the water by gravitation (with a fall of 130 feet) to a filter bed. The man in charge says that there are several valves in the course of the main through which the water can be turned into the stream again, and that these have to be opened occasionally to scour the pipes, in order to keep them clear of sand and mud. The filter bed, which is situated on some high ground close to the village, and within 200 yards of the railway station, seems to have been made when the company was first formed, and not to have been much disturbed since, except for renewal of sand in a way presently to be described; at any rate, I am told that it has not been opened out for the last thirteen years. It is constructed of brick and mortar, forming a tank $24\frac{1}{2}$ feet by 49 $\frac{1}{2}$ feet, and of unknown depth. Surrounding it on three sides in the form of a horseshoe is the service reservoir, covered in, and, I am told, constructed of brickwork with a coating of cement. It is said that the filtered water enters this reservoir through holes in the walls of the filter bed. The filtering medium is said to consist of 4 or 5 feet of gravel and fine sand, with a layer of cobblestones at the bottom of the tank, but, as will be seen, the thickness of the sand varies immensely at different times. This is the method followed: Once a year, after the clogged surface layer of sand has been removed, about 150 cartloads of fresh sand are poured in. This sand is procured from the banks of the Wear close by, having been deposited by floods, and the Wear above this point receives the untreated sewage of a large population, both urban and rural. The water is turned on to the filter bed, and allowed to run through it until the surface layer of sand begins to get clogged, a period which varies from ten days to three weeks, according to the

state of the water. The water is then turned off, and the bed allowed to dry, when the man in charge skims off about an inch of mud and sand, and delves the new surface to a depth of a foot or so. The water is again turned on, and the same process is repeated throughout the year until the sand has been in the main removed, when another 150 cartloads have to be filled in. The process of paring the surface of the filter was done in my presence, and I was told that the level of the sand was then at its lowest, as it was time for its periodic renewal. At that time the surface of the filter was 5 feet 5 inches below the level of the overflow pipe, and I was told that $3\frac{1}{2}$ feet of additional sand was to be thrown in, so that the thickness of filtering medium varies as much as $8\frac{1}{2}$ feet. As has been noted above, the filter bed is surrounded on three sides by the reservoir; on the fourth side is well-manured garden ground, extending up to the wall of the filter bed, and as the wall is made apparently of ordinary brick and mortar, and is dilapidated in many places, there is no doubt that in time of heavy rainfall the soakage from this garden gets into the filter bed. The reservoir is said to contain sufficient water to last for a fortnight if the supply is turned off at night. On the town side of the reservoir is the valve pit containing the pipe from the stream to the filter bed, as well as the distribution main from the reservoir to the town, and these two are joined together by another short main, so that the water from the burn can be turned into the town without passing through the filter bed. This, however, is said never to be done."

The state of things here set forth is sufficiently deplorable, and if I add that the bowel discharges of typhoid patients were prior to the outbreaks chronicled finding their way into the stream above the intake, there can be little wonder at the resulting dissemination of disease by the water of that stream when allowed, with such poor attempt at purification, to enter the distributing mains. Deploable as was this state of things at Chester-le-Street, a larger question is behind it—namely, how far does the case represent the condition of water services in our country? The question is of serious import to the community, affecting as it does the public health in no mean degree. If filtration in its most perfect features does not arrest all the bacteria with which water is infested in its natural, and oftentimes polluted, condition, what can be said of water which is subjected to only an elementary process of filtration? If it be contended that water from whatever source will not convey the means of harm when properly filtered, I for one will not quarrel with people who rely on that filtration, if only it be assured that the method of purification is indeed perfect so far as all reasonableness can demand, and such as shall reduce the germs in the water to less than 100 in each cubic centimetre, so far as development is concerned. If filtration is to be our safeguard, let it be of a kind to prevent all cause for cavil by those who look askance at the theory of the safety to be found in it. I must add one qualification to my adherence to the trust to be placed in efficient filtration, and that is my opinion that the water to be filtered shall be a water free so far as can be determined from even the risk of pollution. I refer, of course, more particularly to risk of excremental pollution. What I would like to see undertaken is a comprehensive survey of the several local and other water supplies in use in our country, all our gathering grounds, filter beds, methods of distribution and the like finding place in the scope of such an inquiry. The matter would doubtless take much time, but that would be a small matter if power were given to the department of State carrying out the inquiry to order the remedying of all defects of moment that were found to be existing. If we have regard to the valuable series of reports now available in the cases in which the Medical Department at Whitehall have made local inquiry into the sanitary circumstances of districts in England and Wales, we shall find that very seldom is the water service such as to prove satisfactory to that Department. But dissatisfaction without the power of remedy is but poor comfort to those desirous of righting the wrong.

Before I leave for the time this interesting subject of river water and filtration in relation to typhoid I should like to refer to one other instance of riverborne typhoid, that, namely, of the river Wear, which furnishes the water supply of Bishop Auckland. The data which I give in the appendix (No. 194) will show in a way not to be gainsaid that the inci-

dence was on the houses of consumers of the public supply from the river, even down to four cases in the village of South Church, in four houses taking the same river supply, to the exclusion of all other houses in that village and all houses in surrounding villages using other water. The waters of the river are undoubtedly grossly polluted above the intake of the supply. The Wear receives the sewage of all the towns in the upper portions of the valley, and, in addition, the raw sewage of several thousand people within a few miles of the intake, not including that of some thirty houses in the town of Bishop Auckland itself. But the water is filtered through a natural sand and gravel bank, the chemical analysis of the filtered water showing it to be of much greater purity than that of the river in its natural state. Yet the water is frequently, when supplied to the mains, quite turbid, thus giving evidence of the inefficiency of the method of filtration adopted. In his report for the quarter ended June 30th, 1893, Dr. Eustace Hill, the health officer for the county of Durham, states that the "county analyst reported of a sample of water taken from the mill race just below the entry of sewage from houses at West Mill and Daisy Bank, and Latherbrush, 'that this sample yields very faint indications of the presence of actual sewage pollution.'" He proceeds to state very truly that the chemical purity of a water is no indication that it can be consumed without danger, and that at Bishop Auckland the filtration is not always effective; whilst there is evidence of the entry into the river just above the intake of sewage containing the specific contagium of enteric fever, at a time coincident with the outbreak of typhoid which I have chronicled in the appendix. It seems that the methods here adopted would not bear the scrutiny which Professor Koch would bring to bear upon them, and that if cholera were ever to find a footing in the upper reaches of the Wear whilst the conditions obtaining in 1893 are allowed to persist in the matter of a water supply drawn from that river, the chances are that Bishop Auckland will suffer very heavily. This instance, to my mind, sets forth very clearly the folly of trusting to so-called filtration, done in a manner which science has now shown to be short of the requisite. Filtration can only be relied upon when it fulfils the conditions laid down by Professor R. Koch, namely, when it secures a water with less than 100 germs capable of development in each cubic centimetre of filtered water, and where the other requisites of bacteriological examination and the like can be fulfilled.

WATERBORNE TYPHOID FEVER OF ACCIDENTS.

It is conceivable that with our complicated machinery for the supplying of large populations with drinking water there would occur from time to time accidents of a nature to be deplored on account of their far reaching results of a harmful character; and so it is, for the history of waterborne typhoid is not without cases where the outbreaks have been directly the result of accident. I may recall attention to the Lewes epidemic of 1874 (No. 71), brought about by the leaving open of the valve of the intake pipe by some children. To this case I have already made reference in other connection, and so I pass on to consideration of additional instances where accidents have been concerned in the cause of outbreaks. One of the most curious of its kind was the outbreak at Perth in 1880 (No. 112), which lasted from May to November, causing 162 attacks and 21 deaths. It happened in this wise. The sewage of the city was disposed of in the river Tay, and quite close to the place of outfall into the river the mains of the public water supply cross from the filtering beds to the city. On a particular day some repairs were needed to the pipes, and by some error the sewage-polluted waters of the river were allowed to find entry to the distributing mains already charged with filtered water. On the next day succeeding there began an epidemic of diarrhoea in the city, and this was followed at the expiration of a week by an outbreak of typhoid, a circumstance by no means unusual in the case of waterborne typhoid, as witness, for example, the instance at King's Lynn. When we state that record of this remarkable case comes from the pen of Dr. Simpson, now health officer of Calcutta, it will be allowed that it demands credence. Of the Bangor epidemic of 1882 (No. 141) much was heard at the time, and after the issue of the report made to the Local Government Board by Dr. Barry. No fewer than 543 cases

and 42 deaths occurred, and some attempt was made to exclude water as the cause of the disaster. This entirely failed, however, to convince any unbiased mind as to the truth of the report, which unhesitatingly put the fever down to the water service. The town was no doubt deserving of a certain amount of commiseration for the lamentable circumstances. There were those who lost their lives by their persistent disregard of the theory of a waterborne pestilence; and yet after all the maledy was brought about by an accidental act, if one may call a flood a matter of accident.

The facts leave no doubt that the river from which the water supply of the place was obtained was polluted some 700 yards above the intake by the excreta of typhoid patients cast into a creek which carried them by means of a rubble drain to the river. The flood which occurred in early July had for its result the bursting of a main, with consequent disturbance of reservoir and filter bed; and this disturbance was followed by a widespread and simultaneous epidemicity of the disease, the fever blazing forth after the lapse of a fortnight following on the bursting of the main. The water was much discoloured after the accident, and smelt badly. Houses not taking it were altogether exempt from fever. To add to the discomfort of those who had much to say by way of doubt of the theory of water, it was pointed out that the filtering beds were inefficient and dirty. And then, again, it can hardly be expected that a river can be polluted by the specific germs of typhoid without grave danger of mischief resulting, especially where the method of filtration is in any wise faulty. Therefore, whilst we may class the instance in our chapter of accidents, it nevertheless remains also as a case deserving of much censure that there should have been permitted to remain such a source of danger to the public water service as the disposal of excrement from houses so situate as to render the pollution of the service possible. If it be held that accidents as such cannot be guarded against, I must enter the lists and give it as my opinion that the health of a community should not be at the mercy of a child, or of an ignorant householder who is content to get rid of his domestic filth without regard for decency or safety. The instance of Perth is probably unique, but it is painful to think of the consequences of any damage or leak occurring in connection with riverborne water pipes, in the same way as it is dangerous to have pipes for water and sewage laid side by side without the greatest of care that any possible exchange of contents is guarded against.

GATHERING GROUNDS AND WATER POLLUTION.

Where drinking water is derived from the surface drainings, the importance of having a gathering ground free from all possible means of pollution is self-evident. And yet to read the history of waterborne disease, one would imagine that to secure a gathering ground that should not directly contribute to the contamination of the supply was a matter of but little concern for those charged with the safeguarding of the public health. I have already had occasion to make some reference to this subject under one or more of the preceding subheadings, but not directly as matter of gathering ground so much as of pollution of streams and the like by surface drainage. This question of the relation of typhoid to the surface pollutions to which water is subjected while in process of collection is one that demands some consideration. We have recently seen some large corporate bodies brought to book on account of the disgraceful conditions which have been permitted to exist along the route of water collection, and to these I shall have to refer in this connection. It will be well that I should make special reference as matter of first instance to a few cases of polluted gathering grounds so far as the facts appear in the appended tables. I will take half a dozen instances. The first is by no means the least interesting. I refer to the Blackburn outbreak of 1881, investigated by Dr. Hubert Airy (No. 128), with its 280 attacks. The case is indeed of such vast importance as showing the conditions prevailing when Dr. Airy visited the borough that I am sure I shall be pardoned if I quote even somewhat lengthily from his report, only promising that the state of things to be now described in narrative obtains to-day. I cannot do better than reproduce Dr. Airy's account of the risks to which the old waterworks supply was exposed by reason of the circumstances in which the water was gathered.

"Now it is evident that this water supply of Blackburn runs the risk of pollution at its several sources. There is risk at the gathering ground above Pickup Bank; there is risk at the White Birk Colliery of some accident similar to that which befell the Caterham well; and there is risk at the well on Revidge, for houses are pretty numerous round about, and the soil is a porous sandstone rock. Moreover, as regards the water from Pickup Bank, there is risk at very many points along the route by which it is conveyed to the town. The stone culvert is of rough construction, built of the ragstone of the district in rude wedge-shaped lumps, fitted together without mortar or cement, but well bedded in thick puddle; and remembering that this culvert has lain for more than thirty years, only three or four feet deep, on the slope of the hill side, with a constant tendency to increase of pressure on the upper side and lessening of pressure on the lower side, it can hardly be supposed that the structure is still sound throughout. Indeed, on one or two occasions at different points the crown of the arch has fallen in, and probably at a hundred points it has yielded more or less, so as to admit a leakage of subsurface water on the upper side. The Corporation have been sensible of the danger involved in this condition of things, and have, some time back, taken pains to prevent the surface water from lodging on the upper side of the mound which overlies the culvert, by cutting trenches and laying drain pipes to carry it away either under or over the culvert. An inspection made last autumn (1890) by the health officer (Mr. Stephenson) and the inspector of nuisances (Mr. Frobisher) revealed the presence of dangerous nuisances in the shape of town manure on the pastures immediately above the line of the culvert. Freedom of manuring was expressly reserved to the neighbouring owners, tenants, or occupiers by the Waterworks Act of 1845. The only remedy the Corporation can use is to refuse to sell manure to the farmers on these lands. They cannot prohibit the manuring of the land, and the farmers can get manure elsewhere: danger from manuring, therefore, still remains. There is also the sewage and ordure of Belthorn, the village on the crest of the hill above the line of the culvert, to be taken into account. At the time of construction of the waterworks Belthorn had no sewer nor cesspool, but disposed of its slops and excreta close around the dwellings. Of late years the house slops have been received in a roadside sewer, delivering into a watercourse which formerly was impounded in a little 'lodge' close above the culvert, and used to supplement the supply from Pickup Bank. Even to the time of my visit the conduit remained open at this point, but the lodge had long before been emptied by a pipe carried under the culvert. Still it has occasionally happened that this pipe has been choked with rubbish or with snow, and the water has half filled the lodge before it has been possible to clear the pipe again. The water bailiffs, however, declare that the water in the lodge under these circumstances never reached the open conduit. Again, there are one or two other points where sewage from Belthorn has to pass over or under the culvert, and where the accident of a defective joint might admit impure water to the latter. The drainage from one row of houses goes into a cesspool on the hill slope. The cesspool sometimes overflows, and the liquid runs down a lane and enters a drain which passes under the culvert. Even in the last twenty yards of its course, before it discharges into the Guide reservoir, the culvert is in manifest danger of receiving sewage from the neighbourhood of a row of cottages (Shorrocks's Row) in the village of Guide (see plan annexed). The slops from these cottages are thrown out partly in front into the road gutter, which carries them over the culvert with no security against percolation except the bad of puddle in which the culvert is wrapped, and partly into a 6-inch pipe drain at the back, which, at the lower end of the row, is carried under the last house and across the road to join a larger stone drain from a higher part of the village."

The above is sufficient to show that the gathering ground was by no means free from sources capable of seriously polluting the water collected in the reservoirs; and Dr. Airy goes on to describe the manner in which he thinks actual pollution may have been brought about by way of the drainage from some privy pits within nine yards of the culvert at one part of its course. Percolation of the contents of these privy pits was demonstrated at the point where those con-

tents passed over the stone culvert, and a case of unequivocal typhoid occurred in February in one of the houses using one of the pits. Moreover, the discharges of the patient were cast into the privy, and though the use of carbolic acid powder is said to have been made, in so far as the stools were concerned, at any rate no such attempt at disinfection was made in the case of the slops and rinsings of vessels. All alike could find their way to the culvert. And even so, Sir Charles Cameron has stated that he has succeeded in developing typhoid bacilli in large numbers from dejects treated with carbolic acid.² In the next month (March) the disease suddenly blazed out in Blackburn, with 149 cases, followed by 61 in April. Dr. Airy shows that the distribution of the water, complicated as it was, fitted in with the theory of

PLAN OF A PART OF THE BLACKBURN WATERWORKS, 1881.

contamination by the excreta of the single case of typhoid just referred to, whilst the widespread and slight incidence on the large population served equally fitted the theory, since, if the one case of disease contributed all the polluting agent then the amount would be very small in relation to the immense body of water to be infected. The heaviest incidence was on that part of the borough served by the reservoir chiefly concerned in the pollution to be derived from the specific evacuations. The case against the water to my mind admits of little room for doubt, and the lessons to be learned from the facts so admirably detailed by Dr. Airy are the folly of collecting water from a gathering ground subject to manurial and other means of probable pollution of the

² BRITISH MEDICAL JOURNAL, August 11th, 1894.

water so collected, and the necessity of looking after any disease within the area of drainage of water, rather than leaving the matter to the chance operations of an unskilled labourer, as was done in the case of the initial attack, which very probably was the starting point of the deplorable epidemic which lasted from March till May of 1881. Another instance of most foul conditions obtaining around the water used by a community subsequently invaded by typhoid was that of Barnoldswick, in Yorkshire, in the spring of 1883 (No. 146), where 48 cases occurred. The well here in question was, we are told by Dr. Atkinson, the health officer, fed from ground saturated by sewage, and itself situate between two sets of cesspools which intercommunicated, fever presenting in some of the very houses draining to the cesspools. Small as were the proportions when compared with the epidemic just chronicled, I much doubt if a case more deserving of censure of the sanitary authority can well be imagined. The people were for all the world drinking their own excrement, and veritably consuming the poison of typhoid. At Cowpen, where enteric seems to be almost endemic, there was an epidemic consisting of 74 cases and 13 deaths in the spring of 1884 (No. 161). Here the water was derived from a stream which received the drainage of highly manured fields on which human ordure was deposited for manurial purposes, and the heavy rains of the winter months preceded the outbreak. In the case now to be referred to, three farmsteads were situate on the area from which the water was collected. I mean that of Swansea in 1885 (No. 161), where nearly 600 attacks were recorded, and nearly 50 deaths were registered, in two months of the summer. At two of the three farmsteads there occurred, it is supposed, cases of typhoid, and the evacuations of the patients under the local conditions and methods of treatment could not fail to gain access to the reservoir through the medium of the watercourses proceeding from the houses. The fever outbreak was continuous with the service of water from the particular reservoir subjected thus to specific contamination, those districts outside this supply totally escaping. It is but right to state that immediately information was received by the sanitary officials of the suspected cases at the farms, and the danger to be apprehended therefrom, the water from the implicated reservoir was cut off.

As testifying to the fact that it was to the consumption of this water that the fever was due, it was found that at the time at which the action of cutting off the water might be looked to, to bring about a decline in the number of new cases, such declination did, as a matter of fact, take place. But the lesson here is again plainly written, namely, the folly of having within the area of the water drainage system any dwellings from which danger may be apprehended in the not unlikely event of specific disease manifesting itself on the premises, where, indeed, the methods of excrement disposal are such as cannot be regarded as absolutely to be relied upon as without the possibility of accident to the water service. Farmsteadings, with their invariable dirt and litter, are the least desirable dwellings to have near a gathering ground, at any rate, as we know such places in general. The instance of the outbreak so recently as 1891 at Rotherham, Rawmarsh, and Greasbrough, will still be fresh in the minds of many people, and its lessons are sufficiently important to warrant me in bringing the chief facts to the remembrance of any who may be without intimate knowledge of them at the present moment. The two former towns, and a definite but small part of the last, had a water service in common, furnished by the Rotherham Corporation. This service was from two gathering grounds and two wells. These gathering grounds (see No. 190) were subject to all manner of polluting media, especially one, the water from which had great bulk (67 per cent.) of the total cases occurring, and these numbered in all 251, with 35 deaths, from October to December. The water supply was the only community of condition in the invaded area. Now, the pollutions to which the gathering grounds were exposed comprised such dangerous elements as the drainage of highly-manured fields, on which were deposited the refuse of farmyards and the contents of privy middens; and in addition the sewage of whole villages found its way into the water; and, to crown all, the filtering beds had none of them been cleansed since 1885, one, indeed, not since 1881, analysis of the water for a series of years bring of

a compromising nature. That there should have been found in England such a combination of deplorable conditions obtaining in connection with the water service of one of our towns as has been the case at Rotherham is a sure sign that our boasting of our immense progress in matters sanitary is rather premature. With different climatic conditions in our country, who would like to predict what would happen in a time of adjacent cholera?

To close this sickening array of facts as to the manner in which potable water is drawn from the surface of sewage-laden land, I take note of the case of Atherstone (No. 199), where the outbreak of 1893 was related to the pollution of the water by way of a piece of common land thickly covered with animal ordure; a large pond also contributing its mud and filth to the pollution, whilst the collecting tank had in its near vicinity a place of defecation for numerous tramps. I have referred somewhat fully to this outbreak already, in connection with the question of levels of mains as affecting the distribution of typhoid, and so I need not here recapitulate. But that a piece of ordinary common land should have been allowed to furnish water by drainage for a town seems scarcely credible. Nevertheless, the fact remains that Atherstone was content to see its water collected in the way described, with the results that will always follow on such a state of affairs. The whole subject of the relation of gathering grounds to typhoid enters so largely into the history of those outbreaks which have been traced to water as a cause, that I have felt no hesitation in thus lengthily speaking of the matter; and it seems to me that it is one that needs much more consideration than has hitherto been paid to it, since we see that some of the most glaring instances on record are of quite recent date. The entire question of surface drainage in so far as drinking water is concerned, calls for remedial action on the part of our companies. Far better trust to polluted waterways, such as rapid rivers, than to the constant presence of infiltrating human ordure, or the rank sewage of villages where disease may at any time become epidemic. Indeed, with efficient filtration, I would much rather see my drinking water coming from a polluted river than from the surface of meadows heavily manured by the visible refuse heaps collected from privies and the like. For one thing, the chances of a river ridding its waters of the harmful qualities of the polluting media are much greater than in the case of water gathered from saturated ground full of abominations, close to the tanks and reservoirs or to the streams which feed the service pipes and places of storage. Of two evils I would choose the least likely to cause mischief.

CHURCHYARD DRAINAGE IN RELATION TO TYPHOID FEVER.

Man, however, does not appear content to pollute his drinking water by the voided filth of the living, but is too often careless in the matter of contaminating his supply by the drainage from the resting places of the dead, and thus it comes about that danger arises from the proximity of burial grounds to the areas of catchment for water impounding purposes. I will briefly refer to two instances in which the proximity of churchyards to sources of drinking water was seriously held in question. The two cases are wide apart in point of time and locality, the one being at Malpas, in Cheshire, in 1871 (No. 37), and the other at King's Lynn in 1891 (No. 189). At Malpas the churchyard has been in use for for many centuries, and not only was it situate on porous soil, but it was so located that all the decomposing animal matter getting away was led to the source from which the water supply was obtained. In the case of King's Lynn, the drainage of a churchyard into the Gaywood river, which furnishes the public water supply, was only one of very numerous sources from which the river derived pollution. Still these two instances serve to indicate the fact that places of burial are at times so placed in relation to water services that their natural drainage finds its way to the water drunk by man; and it does not want much thought to come to the conclusion that their proximity to sources of supply is, to say the least, very undesirable.

SIXTY-THIRD ANNUAL MEETING OF THE
BRITISH MEDICAL ASSOCIATION
IN LONDON, 1895.

THE MEDICAL INSTITUTIONS OF LONDON.

(Continued from page 1843.)

THE MEDICAL SOCIETIES OF LONDON.

By JAMES BLAKE BAILEY, B.A.,

Librarian of the Royal College of Surgeons.

THE material for writing a full history of the medical societies of London is very scattered, and is of a most meagre description. It is well nigh impossible to get a full account of many of the societies which have now disappeared. The chief cause of this is that their minute books have either been destroyed or remain in the hands of private persons and so are inaccessible. It would be well in future if at the dissolution of any society steps were taken to have all its minutes and records preserved in some public library, and perhaps the hint may not be out of place that if any of the minute books of societies already defunct are now in the possession of former officers, they might be deposited in some library where they would be cared for, and be accessible to persons interested in such matters. The migration of the profession from east to west is reflected in the homes of the societies; from the City proper they moved to Lincoln's Inn Fields and neighbourhood, and from thence to the district round about the present fashionable medical quarter of the metropolis. The speculation of the present day is shown in the rapid growth in recent years of societies directed to the study of special organs. This has now reached such a stage that there is hardly any department of practice which has not its special society. Before the establishment of the Medical Society in 1752 the Royal Society was the means by which medical men communicated their discoveries and published their cases. Dr. Fotherby has estimated that the medical papers (including Anatomy and Physiology) in the *Philosophical Transactions* up to 1648 number 1,630.

A good account of the Medical Society of London and some of the other early ones is to be found in the oration by Dr. Routh before the Medical Society in 1839. At the jubilee of the Hunterian Society in 1829 Dr. Fotherby gave an historical sketch of that Society. Sir Edward Sieveking did the same for the Royal Medical and Chirurgical Society in his address of welcome to the Fellows at their new premises in Hanover Square. The best account of the older societies is to be found in the late Mr. J. F. Clarke's *Autobiographical Recollections of the Medical Profession*. The societies connected with the various hospitals, being of a semi-private character, are not included in this paper.

MEDICAL SOCIETY.

This Society was established in 1752 with a view to collect and publish medical observations and inquiries. It must not be confounded with the Medical Society of London, from which it was quite distinct. The Medical Society published 6 volumes of *Medical Observations and Inquiries*. The first paper is dated 1753, and the sixth volume was issued in 1781. The full title of the set is *Medical Observations and Inquiries by a Society of Physicians in London*. This again is misleading, as there was in existence a "Society of Physicians" which was started about 1704, and which owed its origin chiefly to Dr. Alexander Russell. Its meetings were held at Old Slaughter's Coffee House, and its membership was confined to Licentiates of the Royal College of Physicians. According to the *Medical Register* for 1783, Dr. William Hunter was at that time President of the Medical Society. Hunter died in March, 1788, and as the last volume of *Observations* was issued in 1784, it is probable that the Society ceased to exist at about that date. The origin of the Medical Society is thus stated in the first volume of the *Medical Observations*: "A few years ago some physicians in London agreed to meet together for

their mutual improvement in the practice of their profession The persons who formed this Society were either such as had the care of hospitals, or were otherwise in some degree of repute in their profession, and, consequently, had frequent opportunities of making observations themselves, and of verifying in the course of their practice the discoveries of others. When difficult cases occurred to any of them the rest were consulted, and the method of cure which appeared most likely to be attended with success was tried and the event communicated. When these meetings had continued a considerable time, some of the members became desirous of making the public partakers of the advantages that might be derived from such an association. Accordingly they, with some other physicians, formed themselves into a Society for collecting and publishing Medical Observations and Inquiries." There is a copy of the laws of this Society and a list of its members in the British Museum.

THE MEDICAL SOCIETY OF LONDON

was founded chiefly by the exertions of Dr. Lettsom in 1773, "to give the practitioners of the healing art frequent opportunities of meeting together and conferring with each other concerning any difficult or uncommon cases which may have occurred, or communicating any new discoveries in medicine which have been made either at home or abroad." The first meetings were held in Dr. Lettsom's house; the number of members was originally limited to thirty physicians, thirty surgeons, and thirty apothecaries. The early days of the Society were marked by much dissension amongst its members, and so few attended the meetings that sometimes a quorum could not be obtained. In 1776 the home of the Society was in Crane Court, from whence it moved in 1783 to Bolt Court, Fleet Street. In 1800 a lease was taken for twenty-one years of premises in George Street, Hanover Square, after which the Society moved to its present quarters in Chandos Street, Cavendish Square. Dr. Lettsom presented to the Medical Society the house in Bolt Court where the meetings were held; it was to remain the property of the Society so long as the number of its members did not fall below ten; in the event of this happening the house fell to Dr. Lettsom's legal representative. At the time of the amalgamation of the Westminster and Medical Societies it was thought desirable that some definite arrangement should be come to respecting the house, and on the heir-at-law (Mr. John Lettsom Elliott) being approached by the officers of the Society, he very generously waived all claim to the property. Dr. Lettsom also established the Fothergillian Gold Medal, which was afterwards permanently endowed by Dr. Anthony Fothergill. This latter gentleman was not in any way related to the Dr. Fothergill in whose memory the medal was founded. This medal was given at irregular intervals down to 1888; the absence of competitors for the medal caused the Council to apply to the Charity Commissioners for a new scheme to govern its future award. In 1891 the new conditions were approved by the Commissioners; by this scheme it was decided that the charity should be applied by the trustees in providing a prize to be awarded once in three years, of a value not exceeding 60 guineas, either in the shape of a medal or an honorary premium. The first award under this scheme was made in 1893 to Dr. Gowers. The Lettsomian Lectureship was established in 1850 in honour of the early benefactor of the Society. In its early days the Society also gave silver medals for the best paper read at its meetings. It was mainly through dissatisfaction at the way the affairs of the Medical Society were carried on that the Medical and Chirurgical Society was established. One grievance was the continued re-election of Dr. James Sims as president, which office he held for twenty-two years. Dr. Sims seems to have had an eye to the main chance, for in 1800 we find that the Society paid him £50 for books, and also agreed to pay his wife an annuity of £30 should he predecease her. In 1830 the number of members had fallen to 60, and in that year it was decided to amalgamate with the Westminster Medical Society. The amalgamated Society prospered exceedingly, as many as 60 new members being sometimes elected at one meeting. The celebrated picture by Medley of the founders of the Society hangs in the room in Chandos Street; it contains 25 figures of the principal men in the

* See account of Westminster Society.

metropolis at the time the picture was painted. Jenner was not in the original painting, but was introduced subsequently. The engraving by Braunwhite was partly finished before this was done, and a piece of copper had to be let in the plate so that Jenner's head and shoulders might be engraved on a spot previously occupied by background details. The publications of the Medical Society did not appear with any regularity until recent years. In 1792 the first volume of *Memoirs* was issued; of this series there were six volumes, the last appearing in 1806; then nothing was published until 1810, when vol. i of the *Transactions* was issued; after this there is a great gap, the Society not publishing any report of its meetings until 1816, when *Transactions* (new series, vol. i) appeared; the new series, like the old, was limited to one volume. In 1831 another vol. i was issued, and in the following year vol. ii appeared. Then comes a gap again until 1874, when vol. i of the *Proceedings* was published; since that date they have appeared regularly.

MEDICAL SOCIETY OF GREAT QUEEN STREET SCHOOL.

There was another "Medical Society" started in 1779. This was connected with the Anatomical School of John Sheldon and Andrew Blackall, in Great Queen Street, Lincoln's Inn Fields. In the library of the Royal Medical and Chirurgical Society there is a copy of the laws of this Society. The full title runs as follows: "Laws and Regulations of the Medical Society, instituted at the Anatomical Theatre, Great Queen Street, Lincoln's Inn Fields, December 19th, 1779." The date of publication is 1784. Though called simply "Medical Society" on the title page of the laws, the name in the form of diploma is given as "Societas Medica Londinensis." In the list of members, an asterisk is prefixed to those who had occupied the presidential chair. From this it appears that John Sheldon, F.R.S.; John Jebb, M.D., F.R.S.; Robert William, M.D.; Adair Crawford, M.D.; Andrew Wilson, M.D.; William Bishop; and Joseph Hurlock, had filled the office. One of the rules is that "the President shall wear his hat while in the chair," and another states that "in order to keep up a constant fund, each member shall pay on the first Tuesday of each month one shilling and sixpence."

THE SOCIETY FOR THE IMPROVEMENT OF MEDICAL AND CHIRURGICAL KNOWLEDGE.

was founded in 1783 by John Hunter and Dr. Fordyce. Sir Benjamin Brodie gives the date of its foundation as 1798, but this is an error, as there is in existence a letter from John Hunter to Jenner in which he speaks of the formation of the Society, and offers to communicate Jenner's paper on Tartar Emetic. This was received in June, 1781, and published in the first volume of the *Transactions*. The Society was originally composed of nine members, with a provision that it might be increased to twelve, but that it should never exceed that number. Meetings were held once a month at Slaughter's Coffee House in St. Martin's Lane. The papers communicated were first read, and then discussed and corrected after dinner. The Society issued three volumes of *Transactions*, but after the publication of the third volume it existed only as a dining club. On June 2nd, 1814, the Society was formally dissolved, with the understanding that the minute book should remain in the possession of Mr. (afterwards Sir B. C.) Brodie, the then secretary. At Sir Benjamin's death the book came into the possession of Mr. Charles Hawkins, by whom it was presented in 1862 to the Royal Medical and Chirurgical Society. The minute book contains the signatures of all the members (18 in number) excepting Mr. Henry Clive. There is an interesting entry under the date October 7th, 1798: "There being so much joy and interest of conversation about Sir Horatio Nelson's victory, no business was done at this meeting." The Society was evidently a close corporation, for it is stated that Dr. Bagot was proposed as a member, but that the ballot was not proceeded with when it was discovered that he had taken the office of secretary to another Society; this was the Medical and Chirurgical. There was another Society about this date with a very similar title: "The Society for Promoting Medical Knowledge." Two volumes of *Transactions* were published in 1784 and 1789, under the title of "Medical Communications." The secretaries were Dr. Edward Gray, of the British Museum, and Mr.

Edward Ford, of Golden Square, surgeon to the Westminster General Dispensary.

THE LYCEUM MEDICUM LONDINENSE.

was instituted for the advancement of medical knowledge on January 26th, 1784, under the patronage of Dr. Fordyce and Mr. John Hunter. The meetings were held at Hunter's Lecture Room in Castle Street, Leicester Square. All the essays read before the Society were entered in a minute book, and a Committee was appointed to examine them, with power to send such as they thought proper to Dr. Simmons to be published in his *Medical Facts and Observations*. The Society had three classes of members: a first class, which consisted of those who had taken a degree in physic, were members of the Surgeons' or Apothecaries' Company, or were established in practice in surgery, pharmacy, or chemistry. Members of the second class must have attended at a hospital one course of lectures on anatomy and the practice of physic. The third class was intended for those who had only just entered upon a course of medical studies. The members of the first two classes were required to read to the society dissertations on some subject connected with medicine in the order of their names upon the list. The society gave a medal for a dissertation on a stated subject; the first was gained by Everard Home in 1787 for an essay on The Properties of Pus. Dr. Houth states, on the authority of Sir Benjamin Brodie, that the meetings of the "Lyceum" ceased in 1809, the name of the society, however, appears in the Royal Calendar up to 1815; the same names are given as holding office from 1802 to 1815. Dr. Brasley, who is down as President during these years, died in 1813; this fact almost proves that no return was made to the editor and that the Lyceum was inserted in the pages of the Calendar long after the society had ceased to exist. In March, 1839, £110 7s. was presented by the survivors of the Lyceum to the Society for the Relief of Widows and Orphans of Medical Men; this was the result of £100 invested some years before, which had been allowed to accumulate.

THE [ROYAL] MEDICAL AND CHIRURGICAL SOCIETY.

of London was founded in 1805, and was an offshoot of the Medical Society. It was mainly formed by those who had seceded from the Medical, chiefly on account of the repeated re-election of Dr. Sims as President. The first suggestion of forming the new Society came from Dr. Marcel and Dr. Yelloly; they were soon joined by Ashley Cooper, who took great interest in the Medical and Chirurgical, and became its first treasurer. He was also the author of the first paper in the *Transactions*. In December, 1805, the first meeting of the Society was held at 2, Vernian Building, Gray's Inn. Dr. Saunders, who had been chairman of the preliminary Committee, was the first President, and Dr. Yelloly one of the first secretaries. The first volume of *Transactions* was issued in 1806, and from that date to the present time the volumes have appeared with great regularity. The Society also issues *Proceedings*, in the later volumes of which the discussions following on the reading of papers are fully reported. In 1810 the Society moved to 3, Lincoln's Inn Fields, and afterwards met at Nos. 30 and 37. An endeavour to obtain a charter was made in 1812, during the presidency of Sir Henry Hallard; the cost of the application was raised by subscription amongst the Fellows, and so eager were they, that the whole amount (about £300) was subscribed in one evening. The opposition of the Royal College of Physicians was sufficiently strong to prevent the charter being granted. Another application in 1834 was successful, and the Society took the name of the Royal Medical and Chirurgical Society of London. In that same year they took possession of the house, No. 53, Berners Street, and held their first meeting there on February 3rd, 1835. This house was originally built by Sir William Chambers, for his own residence, here he entertained all the leading scientific and literary men of his day.² The Patho-

² The following anecdote of Chamber's residence in Berners Street, is also related to the Society's history. He was one evening at the house of Sir William Chambers, in Berners Street, seated at a table with Sir Wm. and Lady Chambers and several others, when all at once he perceived the candles flickered and the room and the table around him turned in an instant round on their axis, and the guests went on. Sir William, after a pause, ventured to ask the cause of the accident, fearing he had been overcome by the heat of the room. 'Not at all,

logical, Clinical, and Obstetrical Societies held their meetings at the house of the Royal Medical and Chirurgical Society, which thus became the head quarters in London for the profession. Here the Society remained until 1880, in which year it removed to the handsome premises it now occupies at 20, Hanover Square. Additional space has enabled the Council to still further increase the accommodation for other societies. The Society possesses a fine library of about 40,000 volumes; the utility of this is greatly increased by the Fellows being able to borrow books for use at their own homes. There is also an extensive collection of engraved portraits of members of the profession. The celebrated Chamberlen midwifery instruments are in the possession of the Society. In 1872 the Society undertook to administer the fund which had been raised to found a memorial to Marshall Hall. It was decided that the memorial should take the form of a prize to be given every five years for the best original work done during that period on the nervous system. The first award was made in 1878, Dr. Hughlings Jackson being the recipient of the prize.

THE WESTMINSTER MEDICAL SOCIETY

was founded by Sir C. Mansfield Clarke and Sir Benjamin Brodie in 1809; its meetings were held at the School of Medicine in Great Windmill Street. For some years the Society seemed almost to be an appendage of the school, every student who attended the lectures becoming also a member of the Society. In 1834 it is said to have had about 1,000 members. After the breaking up of the Windmill Street School the Society met in Sackville Street, from there it went back to Windmill Street, then it met in Exeter Hall, and last of all moved to Savile Row. During its first occupation of Windmill Street no rent was paid, and so the Society was in a flourishing financial position; at the other places the necessary rent caused a drain on the funds. The interest in the meetings gradually declined, until in 1843 the Society was reduced to about twelve members; then it took a new lease of life, and at its close it showed 275 names on the books. The Society took the lead in discussing the nature and treatment of cholera during the epidemic of 1832, and in its discussions on the Anatomy Bill it did much to do away with the popular prejudice against that measure. During the presidency of Mr. Hird, in 1849-50, steps were taken for amalgamating the Westminster and the Medical Societies, and during Dr. Murphy's term of office this was successfully carried out. The motion for amalgamation was unanimously agreed to by the Medical Society on March 4th, 1850, and by the Westminster Society on March 28th of the same year. It was agreed that in the amalgamation scheme the President of the Medical Society should be the first President of the new body. Dr. (afterwards Sir) Risdon Bennett held this office, and the first secretaries were Dr. W. Cogswell and Dr. C. H. F. Routh. It was found impossible to unite the two names in the new Society, as the property of the Medical Society was so held that it could not change its name. The name of Westminster, therefore, disappeared, and the amalgamated body was known as the Medical Society of London; its first meetings were held in George Street, Hanover Square. At the time of amalgamation the Westminster had 237 names on its books, exclusive of honorary and corresponding members. The old Society only issued three numbers of *Proceedings*, which contain the record of the session 1848-49. The papers are, however, fairly reported in the medical journals of the day.

THE HUNTERIAN SOCIETY.

The idea of founding a medical society for the East of London originated with Mr. Armiger, Assistant-Surgeon to the London Hospital. Being himself unable to take an active part in the preliminary arrangements for starting the Society, this duty was undertaken by Dr. Cooke, of Great Prescott Street, who, on November 11th, 1818, called a meeting at his residence for the purpose of discussing the desir-

ability of starting the proposed Society. The preliminary meetings do not seem to have been marked by any enthusiasm. The proposers of the scheme, however, persevered, and, having obtained the adherence of Sir William Blizard, called a meeting at the King's Head, in the Poultry, on January 30th, 1819, to inaugurate the Society. A subsequent meeting was held to draw up rules, etc., and on February 11th another meeting was called to elect officers, when Sir William Blizard was elected the first President and Dr. Copquest and Mr. Armiger appointed Secretaries. The original intention was to call the Society "The London Medical and Physical," but, on the suggestion of the President, it was altered to "The Hunterian Society," and "*Ratio Societatis Vinculum*" was adopted as its motto. A room was obtained at the London Orphan Asylum in St. Mary Axe, and there, on April 21st, the first business meeting was held. In 1821 the Society moved to new premises at No. 18, Aldermanbury, and in 1834, as these rooms were required for other purposes, a further move was made to No. 4, Blomfield Street, where arrangements for a tenancy were concluded with the managers of the Congregational Library. Here the Society found a home until the premises were required by a railway company in 1866. In that year the Council was enabled to secure accommodation at the London Institution, where the Society has remained ever since. A library for the use of members was established early in the history of the Society: the first grant was made in 1822 when £50 was voted for the purchase of books, and, very appropriately, the Works of John Hunter was the first book ordered. The *Reports of the Hunterian Society* were first published in 1825, and have been continued to the present day. The first Oration was delivered by Sir William Blizard in 1826, and, with a few breaks, this has been annually kept up.

(To be continued.)

THE ANTITOXIN TREATMENT OF DIPHTHERIA.

OWING to the numerous calls upon the pages of the *BARTSH MEDICAL JOURNAL*, and the large amount of space already given during the past few months to the report of cases of diphtheria treated by antitoxic serum, we are compelled to abstract the reports of the following cases received recently:

Dr. JAMES H. RODGERS (Cardiff) reports two cases: (1) P. W., aged 2 years and 7 months, who had had several previous attacks of follicular tonsillitis, was taken ill on May 8th, and on the following day had a temperature of 102° F., with enlargement of the tonsils. On the following day the temperature was 103.4° F., and on May 11th two patches of white membrane were seen on the right tonsil. On that evening the temperature rose to 104.2° F., the pulse was 152, and the respirations 40, and the whole of the right tonsil was covered with straw-coloured membrane; there was also membrane on the left tonsil, and enlargement of the lymphatic glands. On May 12th the temperature was 104.4° F., the pulse 148, respirations 48. The membrane had extended to the soft palate, and there was a blood-stained discharge from the nostrils. At 4 P.M. 1 drachm of Schering's antitoxin was injected. At 8 P.M. the temperature was 103.6° F., and the patient was restless and prostrate. Next morning, after a good night, the temperature was 101° F., the pulse 112, and the respirations 24. The membrane was easily detached. In the evening the temperature was 99.4° F., and the membrane was clearing. On May 14th the temperature was 97.2° F., the pulse 100 but irregular, and the respirations 20. Membrane remaining on the left tonsil was easily detached. The patient was convalescent, but the temperature remained subnormal and the pulse irregular for a few days. (2) W. W., aged 5 years and 8 months, sister of the first patient, was taken ill on May 14th. On May 16th the temperature was 103.4° F., the pulse 148, the respirations 32, and both tonsils were enlarged and presented straw-coloured membrane. On May 17th the membrane had extended to the palate; that evening the temperature was 103.6° F., the pulse 152, and the respirations 40, and there was prostration. Half a drachm of antitoxin (all that was available) was injected. The temperature at 3 A.M. was 101° F., and the patient passed a better night. At

replied Goldsmith: "but in truth I could not bear to hear that unfortunate woman in the street, half singing, half sobbing, for such tunes could only arise from the extremity of distress; her voice grated painfully on my ear and jarred my frame, so that I could not rest until I had sent her away." It was in fact a poor ballad singer, whose cracked voice had been heard by others of the party, but without having the same effect on their sensibilities.

10 A.M. the temperature was 97.6° F., the pulse 104, and the respirations 20. That evening the patient was practically convalescent, but the temperature remained subnormal for a few days. In both cases there was albuminuria and loss of knee-jerk. Quinine with perchloride of iron was given internally, and local applications of perchloride of iron and glycerine were made from the earliest stage.

Dr. T. Luson (Norbiton, Surrey) reports a case of recovery after tracheotomy. A child, aged 5, was first seen on May 23rd, when the fauces were covered with membrane, breathing was croupy, and the urine contained albumen. On the next day the child was worse and the temperature was 101° F. On May 25th rapid aggravation of the asphyxia rendered immediate tracheotomy necessary, and a silver tube was introduced. Later in the day, when the temperature was 101.4° F., Schering's antitoxin was injected. Next day the temperature was 100° F., and a large amount of membrane was expectorated. Two other doses of antitoxin were given—xv on May 28th and x on May 30th—when the temperature was 99° F. A rubber cannula of smaller calibre was introduced on May 28th, shortened gradually on subsequent days, and withdrawn permanently on June 3rd. The child recovered without any complications.

Dr. H. W. WEBSTER (Rickmansworth, Herts.) reports two cases. (1) A boy, aged 7, taken ill on May 18th, was first seen on the evening of May 19th, when there was membrane on the right side of the uvula, on the right tonsil, and on the pharynx. On May 20th the dyspnoea increased, and in the evening there was inspiratory stridor, aphonia, and retraction of the soft parts of the chest wall. Antitoxic serum (Burroughs, Wellcome, and Co.) 15 c.cm. was injected between the scapulae. At 10 P.M. the child was transferred to the Watford Isolation Hospital, and at 11 P.M. tracheotomy was performed, Dr. Berry, of Watford, giving chloroform. The child was placed in a tent. On May 21st three large pieces of membrane had come away through the tracheotomy tube, the patch on the soft palate was loosened, and no fresh patches could be seen. At 11.30 A.M. 10 c.cm. of serum were injected. On May 22nd no membrane could be seen, and the child breathed comfortably when the tube was temporarily withdrawn. On May 23rd there were two small spots on the right tonsil, but the boy looked well, and was hungry. The urine on this day contained only a trace of albumen. The tube was removed (sixty hours after tracheotomy). He continued to improve, and on May 29th was allowed out. On May 31st a copious morbilliform rash appeared on the legs, and a few spots on the chest. These slowly faded, and had disappeared in five days. The tracheotomy wound healed quickly, and no signs of paralysis could be discovered. (2) The sister of the last patient, aged 4, had sore throat on May 26th, with enlargement of the tonsils and a greyish patch on each. On May 27th a thick greyish-yellow patch covered half the surface of each tonsil, and on the following day it extended to the right side of the soft palate. On May 28th the patch had cleared off the palate. The patient was croupy in the night, and on May 30th there were white patches on both tonsils. At 10 A.M. 10 c.cm. of antitoxic serum from the British Institute of Preventive Medicine was injected, and at 1 P.M. she was removed to the Watford Isolation Hospital. The injection was repeated on June 1st, when the child seemed comfortable and took nourishment. On the right tonsil only there was a thin whitish patch. On June 6th the throat had a normal appearance, and the glands, which had been enlarged, could hardly be felt. There was no albuminuria and no paralysis in this case. In both cases the local treatment consisted of the application of perchloride of iron and glycerine, and of perchloride of iron and subsequently tincture of digitalis internally. In both the diagnosis was confirmed by bacteriological examination at the British Institute of Preventive Medicine. In neither was the temperature at any time observed to be above normal.

Mr. JOSEPH WALKER, M.R.C.S. (Kirkby, near Liverpool), reports a case in a boy, aged 6, who after complaining of sore throat for some days became rapidly worse on May 27th. The soft palate, tonsils, and pharynx were congested, and upon each tonsil was a greyish patch. Some improvement followed treatment by local application of boracic acid, and a solution of perchloride of mercury (1 in 1000) with iodide of potassium and salicylate of sodium internally. The mem-

branous patches continued to spread; breathing became stridulous and the cough croupy. At 10 P.M. on June 1st all the symptoms became aggravated, and there was much dyspnoea. Next day, June 2nd, after consultation with Dr. Carter, of Liverpool, 15 c.cm. of antitoxic serum (Burroughs, Wellcome, and Co.) was injected. Dyspnoea at this time was intense. At 10 P.M. there was slight improvement, but the patient had a restless night with frequent paroxysms of dyspnoea. At 9.30 A.M. on June 3rd he was semi-conscious and livid, with cold extremities; a second injection (7½ c.cm.) was given. At 4 P.M. he was easier and the membrane appeared to be loosening. The improvement continued; several fragments of membrane were coughed up, and at 10 P.M. a third injection (7½ c.cm.) was given. He had a bad night, but next morning there was a general improvement. Large pieces of membrane had been expectorated and the pharynx was clear. The improvement continued, and on June 7th he was allowed to get up. The urine was highly albuminous and of high specific gravity (1030) on June 2nd, but on June 5th there was only a trace of albumen, and the specific gravity was 1020. A portion of the membrane removed on June 4th was examined by Dr. Robertson, of St. Helens, who reported that the swabs contained very few diphtheria bacilli in comparison with the large number of other organisms, but they were quite characteristic.

Mr. H. W. KNOWLES (St. Helens) reports the case of a girl, aged 4, who, after complaining of sore throat for three days, was seen on January 4th with tonsillitis, pharyngitis, and patches of membrane on both tonsils and on the uvula. The glands were enlarged, there was a croupy cough, but no obstruction to respiration. The urine contained one-fifth albumen, and there was a good deal of general prostration. The temperature was 100° F., and the pulse 150; 6 c.cm. of antitoxin (supplied by Dr. Klein) was injected. On the following morning the membrane was still abundant, but the general condition was much improved. The temperature was 99° F., and the pulse 118. On January 6th the pulse fell to 80. The membrane disappeared altogether on the fourth day after the injection. The albumen disappeared on the seventh day, and the child was discharged well on January 21st. The diagnosis was confirmed after bacteriological examination by Dr. Robertson, M.O.H., St. Helens.

Dr. J. MASON (St. Helens) reports a case of laryngeal diphtheria in which tracheotomy was performed in a girl, aged 4. When first seen on January 22nd the child had been ill for a week, and had had a croupy cough for four days. The temperature was 101.3° F. There was slight inspiratory stridor and a hard metallic cough. The tonsils and pharynx were congested. On January 23rd the stridor was greater and the lungs were not expanding freely. On the left tonsil was a patch of greyish-white membrane. At 6.45 P.M. an injection of 5 c.cm. of antitoxic serum, supplied by Dr. Klein, was given. On January 24th, at 10 A.M., the increased cyanosis and difficulty of respiration rendered tracheotomy necessary. A large quantity of membrane was coughed up through the tube, and the breathing became easier. On the following morning an injection of 5 c.cm. was given. The membrane on the tonsils came away during the day, and after two days no more membrane was coughed up through the tube. No fresh membrane formed after the first injection. A trace of albumen was present in the urine on January 22nd, 24th, and 26th. The child made an uninterrupted recovery, and the tube was removed on February 4th. Dr. Robertson found the bacillus diphtherie present in a piece of membrane removed on January 23rd, but not in the secretions from the throat and larynx on January 30th and February 13th.

Dr. JAMES R. PURDY, M.O.H. to the Hutt County Council (New Zealand) reports a case in a patient, aged 35, who on April 18th had a sloughing ulcer on the right tonsil. The temperature was 101° F., the pulse 95, and he complained of pains in the knees and elbows. He was ordered a gargle of biniodide of mercury (1 in 2,000) and salicylate of sodium internally. He was taken suddenly worse on April 20th, and when seen on April 21st, the whole of the roof of the mouth, both tonsils, the uvula, and the pharynx were covered with typical diphtheritic membrane. The cervical glands were swollen, the pulse feeble; 10 c.c.m. of antitoxin from the British Institute of Preventive Medicine was injected. At noon next day the pulse was 96 and much stronger, the temperature normal; the throat was almost clear of membrane, but there was a black slough at the base of the uvula. The glands were smaller. On April 23rd the patient was much better and the slough was separating. On April 29th the man was quite well, but there were two white scars, one on the uvula and one on the pharynx.

Dr. LEONARD B. WELLS (Worcester) sends us a report of the case of a child, aged 3½, who was first seen, after four days of illness, on May 3rd, and found to be suffering from diphtheria. On May 4th, at 3 p.m., the membrane covered both tonsils and started back towards the epiglottis. There was much recession of the lower ribs, cough was croupy, and the membrane had evidently begun to invade the larynx. An injection of 20 c.c.m. of serum (Barrington, Wellcome & Co.) was given. This serum had been kept for fourteen weeks. On May 5th the cough was less croupy, the respiration easier, but the throat was about the same. On May 7th the glands in the neck were much enlarged, but the condition of the throat was much improved and the breathing was easier, though the child was more restless. Another injection of 20 c.c.m. of the serum, newly obtained, was given. On May 8th the fauces were quite clear, cough was frequent and hoarse, but not croupy, and there was no recession of the lower ribs. After this a rapid convalescence was made. The diagnosis was confirmed by bacteriological examination by the Clinical Research Association.

THE ANTITOXIN TREATMENT ABROAD.

Spain.—The *Union de las Ciencias Medicas* of Cartagena publishes the following statistics: The average death-rate from diphtheria at Cartagena was till lately 268, or 8 per 1,000 of population, and 15 per 1,000 of the total number of deaths. Of 166 patients treated with serum, 79 were males and 77 females; the great majority of them being aged from 2 to 3 years. Terraced's serum was used in 129 cases, Roux's in 30, and Behring's in 6. Of the whole number, 21, or 13.46 per cent., died. During the ten years before the introduction of the serum treatment the average number of deaths from diphtheria in Cartagena was 21 per month. During the four months the serum method has been in use the total number of deaths from diphtheria has been 21; in other words, the mortality from the disease has been reduced to one-fourth of what it was.

France.—A decree has been passed appointing a Committee, under the Minister of the Interior, to consider all questions arising under the law of April 25th relative to the preparation, sale, and distribution of therapeutic serums and other analogous products. The Committee is especially charged with the examination of all applications for permission to place such products on the market, and with the carrying out of the inspections enjoined by the law. The Committee consists of the members of the Committee of Management of the Sanitary Services, of the Perpetual Secretary of the Academy

of Medicine, and of eight members nominated by the Minister of the Interior, half to be chosen from among the members of the Academy of Medicine, and half from among the members of the Consultative Committee of Public Health in France.

THE EDINBURGH HARVEIAN FESTIVAL.

THE 113th Harveian Festival was held in the Hall of the Royal College of Physicians, Edinburgh, on June 23rd, when the Orator was given by Dr. Yellowhead, the Physician Superintendent of the Royal Asylum, Carnarvon, Glasgow. After returning thanks for being elected to the President's chair, and for the consideration and compliment paid him by postponing the yearly festival from April 15th to this date, Dr. Yellowhead took as his subject *The York Retreat* and Dr. Daniel Hack Tuke. After a rapid glance at the barbarous treatment of the insane in other days, and the evolution of the old madhouses he alluded to: At length in 1791, a case occurred in the York Asylum which commanded public attention. A lady belonging to the Society of Friends was confined in that asylum, her relatives were refused admission to see her, and the treatment to which she was there subjected aroused their worst suspicions. These suspicions proved to be only too well founded, but it was deemed a hopeless task to reform that asylum, and William Tuke, a Quaker of York, and a member of the Society of Friends, proposed that they should erect a new institution where there should be no concealment, and where sympathy and kindness, not terrorism and punishment, should be the essence of the treatment. In spite of difficulties and discussion, and prophecies of failure, the grand old Quaker held firmly to his purpose. He was resolved that the miserable condition of the insane should be ameliorated, and pleaded and toiled so earnestly that without delay the York Retreat was built, its foundation stone bearing the simple and noble motto: "*Hoc fecit amicorum civitas in humanitatis argumentum.*" A.D. 1792."

Thus did the Society of Friends add another to the lessons of humanity and brotherliness which they had taught the world, and thus did William Tuke when he built the York Retreat unconsciously build for himself an everlasting name, for he inaugurated the wondrous revolution in the care and treatment of the insane of which we only now see the full fruit. Such an example could not but inspire others. Another member of the Society of Friends determined to do for the South of England what William Tuke had done for the north, and in 1789 Dr. Edward Long Fox purchased the estate of Brislington near Bristol, and proceeded to build an asylum thereon, which is still in the hands of his descendants, and is one of the best in England. The Foxes were like the Tukes, a grand race and strict Quakers. The father of the man who built Brislington House was Joseph Fox, surgeon, of Falmouth. An incident recorded of him shows that any profession might be proud to claim him. During the war with France two Falmouth vessels in which he owned a share were sent out, against his strong and remonstrances, under letters of marque to prey upon French commerce, and this they did so successfully that Fox's share of the spoil exceeded £22,000. This sum his partners wished to retain as he had opposed the expedition, but Fox insisted on his claim, lodged the money in the British Funds, and five years later, when the war was over, he sent his son to France to discover and to repay the rightful owners. After much difficulty and delay this noble purpose was accomplished. £22,000 was paid back, and the balance for which owners could not be found was paid some years later to the fund for the Invalid Seamen of France for the relief of "non-combatants." The descendants of this man have been the heads of Brislington House for almost a century. A great grandson is its present head, another great grandson is Dr. Edward Long Fox, the President of the British Medical Association; another great grandson, Dr. Charles Henry Fox, is present as a guest at our festival to-day.

It was natural, though much to be regretted, that the disuse of mechanical restraint, which appeared so wonderful after the long years of its abuse, should have given to this new method of treatment the name of "the non-restraint system;" and it is yet more to be regretted that some of the

followers of these great men of old should have sought with less wisdom than zeal to erect non-restraint into an absolute, imperative, and universal law. William Take was far too wise and reasonable to hold any such opinion. His great-grandson thus places on record the views and practice of the Retreat: "When kindness failed to subdue maniacal excitement, when medical remedies exerted no calming influence, mild forms of restraint were reluctantly adopted rather than maintain a conflict between patient and attendant. It appears from the archives of the retreat that not more than 5 per cent., reckoning night as well as day, were restrained or secluded." "Coercion was regarded at the retreat as an evil—that is to say, it was 'thought abstractedly to have a tendency to retard the cure by opposing the influence of the moral remedies employed'—but at the same time a necessary evil—an unhappy alternative in certain cases." Samuel Take thus writes in his *Description of the Retreat*: "We greatly prefer to lay down no absolute rule of non-restraint, but to refer to our resident officers the exercise of a sound discretion in each individual case."

It is an unworthy narrowing of Take's great work to call it the "non-restraint system." It was far more and greater than the disease of chains and bonds; it was a reversal of the whole tone and methods of former days. It was the substitution of sympathy, encouragement, and kindness for neglect, harshness, and cruelty. It was the recognition of the despised lunatic as a man and a brother, and feeling towards him, and dealing with him as a man and a brother ought. Humanity like this is its own best interpreter; it needs no party shibboleth, and owns no dogmatic rule.

All the best principles of treatment as we practise them today were laid down and practised at the York Retreat. The value of surroundings, of companionship, of occupation, especially out of doors, were fully recognised. A good meal, a wholesome stimulant, or a warm bath were found to be often better sedatives than drugs.

The fame of the Retreat soon spread, and its founders learned with deepest interest that Pinel had been acting on like principles at the Bicêtre, and that a simultaneous reaction wave in favour of the lunatic had visited both lands. The great example was soon followed, and in the beginning of the century the Royal Asylums of Scotland were built and carried out on the same great principles of treatment.

The old Retreat maintains its ancient spirit, and keeps fully abreast of the times. Three years ago its centenary was celebrated at a meeting, within its walls, of the Medico-Psychological Association of Great Britain and Ireland. America, Belgium, Holland, France, Switzerland, Germany, Russia all joined by letter or by representatives on the great occasion, and a resolution, which I had the great honour of proposing, was enthusiastically passed in which the Association placed on record its admiration "of the spirit which animated William Take and his fellow-workers a hundred years ago, its appreciation of the mighty revolution which they inaugurated, and its thankfulness for the beneficent results which their example has secured in the humane and enlightened treatment of the insane throughout the world." Prominent among us on that memorable day was William Take's great grandson. The spirit of the grand old Quaker descended to his children. His son Henry seconded all his efforts and shared his work, his grandson Samuel recorded them in his *Description of the Retreat*, one of the classic books of psychiatry, and his great-grandson worthily carried forward his great work in the ancestral spirit of constant and self-sacrificing devotion.

[Dr. Yellowless then sketched the chief events of the life of Dr. Daniel Hack Take, which were related by a sympathetic hand in the *BRITISH MEDICAL JOURNAL* of March 8th, 1896, p. 565. Continuing he said:]

Psychiatry never had a more eager student, or a more untiring and forgetting one, than Hack Take. A strange case, a new theory, an original and improved treatment instantly awakened his interest, and he forgot sleep, food, and fatigue in inquiry and discussion. He had a singularly open and excited mind, and never dismissed even what seemed absurd without considering whether there might not be truth beneath it. While a man of wide knowledge and broad sympathies, his whole life was really devoted to the study of insanity in all its phases, and to the care of the insane in all

their interests. He had no greater enjoyment than to talk with another alienist on their familiar themes. He contributed largely to the literature of the subject, and such work was a delight to him. His latest important work was a most valuable *Dictionary of Psychological Medicine*, written by many selected contributors, whom no one but Dr. Take could have brought together. He was also for many years joint editor of the *Journal of Medical Science*, an office which he greatly enjoyed, for it brought him into touch with what was newest and best in his favourite subject, and the duties of which he performed admirably.

Not a vivid genius, not an original discoverer, not a brilliant microscopist, he was fully up in all the knowledge of his time, and applied it in the best and wisest way for his patient's good.

No man of his time was so familiar with the world of the insane, at home and abroad, or with the work and the workers there, and certainly no one was so well known in that world as Dr. Take. He was a kind of living encyclopedia, and ultimate referee, on all that concerned the insane, and his death has left a blank in our ranks which no one will even pretend to fill. Of his personal character it is impossible to speak as apart from his professional work, for there was no such separation in his life. The beautiful sincerity, serenity, and truthfulness of the man, his consideration for others, his quick sympathy, his unfailing kindness, his quiet humour, and the high Christian principle which strengthened and beautified all the rest; these qualities which endeared him to us, were the very qualities which made him what he was to the insane, not their physician only, but their guide, comforter, and friend. Thus lived Daniel Hack Take; and

Thus cheerful in the light around him thrown,
He did God's will as if it were his own.

After the Oration the Harveians, to the number of forty, dined in the Library of the College. Dr. Peel Ritchie, the President-elect, was croupier. After the usual loyal and patriotic toasts had been given and honoured, the President gave "The Immortal Memory of Harvey." Thereafter the toast of "The Medical Schools of Scotland" was given by Dr. STRUTHANS, and replied to in a clever and amusing speech by Dr. W. RUTHERFORD; "The Guests" (coupled with the name of Dr. URQUHART, Perth), by Dr. RENTON; "The President," by Dr. ARTHUR ROBERTSON; "The Vice-President," by Sir JAMES RUSSELL; and finally "Floreat Res Medica" from the Chair. The evening was further enlivened by songs from Drs. RUTHERFORD, PEEL RITCHIE, UNDERHILL, and LOCKHART COLLETT, and by stories from Drs. CHUM BROWN and JOHN CHURCH. Altogether the festival was felt to be one of the happiest and most successful of recent years. There were two neophytes who were reported on as having duly partaken of the traditional heart.

ROYAL COLLEGE OF SURGEONS.

COUNCIL ELECTION.

THE ballot for the election of five members of the Council was held on July 4th, with the following result:

Mr. Willett	315
Mr. Treves	325
Mr. Butlin	326
Mr. Alfred Cooper	326
Dr. Ward Cousins	331
Mr. Davies-Colley	340
Mr. Norton	347
Mr. Page	367
Mr. Anderson	310

Mr. Willett, Mr. Treves, Mr. Butlin, Mr. Cooper, and Dr. Ward Cousins were therefore declared elected. Only 60 Fellows voted in person, 621 sent in voting papers by post. The poll was heavy, 180 more votes than last year.

OBITUARY.

THE RIGHT HON. T. H. HUXLEY, F.R.S., D.C.L., LL.D.,
F.R.C.S., &c.

Late President of the Royal Society; Corresponding Member of the
Académie des Sciences; Dean and Hon. Professor of Zoology,
Royal College of Science, London.

Is Professor Huxley, who died at Eastbourne on June 20th. Science mourns her most distinguished champion, and the medical profession has lost one of its most illustrious members. His health had been failing for some time, and some seven or eight years ago the late Sir Andrew Clark warned him that his heart was in a condition which made his hold on life a frail one. Treatment at Maloja, however, by the system of graduated exercise introduced by Oertel, strengthened the failing organ so much that Huxley seemed to have entered on a new lease of life. Four or five years ago he pitched his tent at Eastbourne, almost under the shadow of Beachy Head, being attracted to the place not only by the bracing air, but by the opportunities for gentle hill climbing offered by the Downs. So well did this suit him that until a very few months ago his upright carriage and the springiness of his step made it difficult to believe that his years were already three score and ten.

HIS LAST ILLNESS AND DEATH.

At the beginning of March he was attacked by influenza, with serious lung complications which, in the weakened condition of the heart, more than once brought him to the very verge of death. He rallied so far, however, that during the warm weather in the early part of May he could be carried downstairs, and he appeared for a time to make satisfactory progress. About ten days ago, however, a relapse occurred; embolic nephritis with further cardiac complications came on, and he passed away quietly on the afternoon of Saturday last, retaining consciousness almost to the last. The immediate cause of death was pulmonary embolism. He was confined to his room only a few days, having been in his garden for a short time so recently as the Tuesday before he died. He was attended throughout his illness by Mr. H. D. Farnell, F.R.C.S., of Eastbourne, who had the advantage of consultations on several occasions with Dr. Burney Yeo and once with Sir William Roberts, and the assistance of the Professor's son, Dr. Henry Huxley.

As a patient, Professor Huxley was all that the ordinary doctor, when himself ill, too often is not. From first to last he was perfectly calm, bearing his sufferings without complaint, taking a keen scientific interest in his own case, but leaving the management of it unreservedly in the hands of those who had charge of him. His playful manner and

unsubdued till the end. He jokingly warned one of his doctors not to argue with him on the physiological aspects of his case unless he wished to be "floored," and he offered to demonstrate the femur on his own emaciated limb. The very Sunday before his death he spent some hours in his garden delighting those about him with reminiscences and anecdotes told with nearly all his old wit and felicity of phrase. In one of the crises of his illness, when his perfect equanimity extorted some remark from his attendants, he said that when he was at sea he had sometimes been awakened by the rolling of the ship in rough weather; on hearing the voice of the officers on deck, however, he would quietly turn over and go to sleep again, with the thought that it was their

affair, not his. In the same spirit, when difficulties arose in the conduct of his case, he told his physicians to do whatever they thought right, saying: "That is your business, not mine." In explanation of his docility as a patient he would say that all through his life he had been guided by two principles alone, namely, never to tell a lie, great or small; and always to obey lawful orders. In a word, Huxley died as he had lived, as a philosopher — steadfastly carrying out to the end, according to his lights, Goethe's precept *im Glauben, Glauben, Wahren remain zu leben*.

BIOGRAPHICAL SKETCH.

Thomas Henry Huxley was born, as he himself has told us, "about eight o'clock in the morning on May 4th, 1825, at Easing, which was at that time as quiet a little country village as could be found within half a dozen miles of Hyde Park Corner." His father was one of the masters "in a large semi-public school which at one time had a high reputation." Why he was christened Thomas Henry he did not know, but he referred to it as a curious chance that his parents should have fixed for his usual denomination upon the name of the particular apostle with whom he had always felt most sympathy. Like many other remarkable men, he owed much to the influence of his mother. In his autobiography he says:

"Physically and mentally I am the son of my mother, so completely — even down to peculiar movements of the hands, which made their appearance in me as I reached the age she had when I noticed them — that I can hardly find any trace of my father in myself, except an inborn faculty for drawing, which unfortunately in my case has never been cultivated, a hot temper, and that amount of tenacity of purpose which unfriendly observers sometimes call obstinacy."

His regular school training was of the briefest, a circumstance which he himself accounted fortunate, inasmuch as the society he fell into at school was the worst he ever knew. The boys were simply left to the struggle for existence among themselves, believing being the least of the ill-

T. H. Huxley

thing from metaphysics to heraldry," Guizot's *History of Civilization* and Sir William Hamilton's *Philosophy of the Unconditioned* in particular making a deep impression upon him, though he owns that of the latter work at least he could not possibly have understood very much.

As he grew up his great desire was to be a mechanical engineer, but the Fates were against this, and while very young he commenced the study of medicine under a medical brother-in-law. He owns that in later life he was occasionally horrified to think how little he ever knew or cared about medicine as the art of healing. The only part of his course which really and deeply interested him was physiology, "which is the mechanical engineering of the human body." The extraordinary attraction he felt towards the study of the intricacies of living structure nearly proved fatal to him at the outset. When between 13 and 14 years of age he was taken by some older student friends to the first *post-mortem* examination he ever attended. Throughout his life he was "most unfortunately sensitive to the disagreeables which attend anatomical pursuits," but on this occasion his curiosity overpowered all other feelings, and he spent two or three hours in gratifying it. He did not cut himself and none of the ordinary symptoms of dissection poison supervened, but poisoned he was somehow, and he sank into a strange state of apathy. He was sent to a farmhouse in Warwickshire and soon recovered, but for years he suffered from occasional paroxysms of internal pain, and from that time, to use his own words, his constant friend, hypochondriacal dyspepsia, commenced his half century of co-tenancy of his fleshly tabernacle.

As a medical student he worked extremely hard when it pleased him, and when it did not—"which was a frequent case"—he was, he confesses, extremely idle (unless making caricatures of his pastors and masters can be called a branch of industry) or else wasted his energies in wrong directions. He read everything he could lay his hands upon, including novels, and took up all sorts of pursuits, to drop them again as speedily. He says: "No doubt it was very largely my own fault, but the only instruction from which I ever obtained the proper effect of education was that which I received from Mr. Wharton Jones, who was the lecturer on physiology at the Charing Cross School of Medicine. The extent and precision of his knowledge impressed me greatly, and the severe exactness of his method of lecturing was quite to my taste. I do not know that I have ever felt so much respect for anybody as a teacher before or since. I worked hard to obtain his approbation, and he was extremely kind and helpful to the youngster who, I am afraid, took up more of his time than he had any right to do. It was he who suggested the publication of my first scientific paper—a very little one—in the *Medical Gazette* of 1845, and most kindly corrected the literary faults which abounded in it, short as it was; for at that time, and for many years afterwards, I detested the trouble of writing and would take no pains over it."

In 1845 he passed the first M.B. examination at the London University, in which he obtained honours in physiology, but failed to secure the medal, being, as he said in a speech at University College, "thoroughly well beaten" by Dr. Hansom, of Nottingham. In the early spring of 1846, having finished his obligatory medical studies, though still too young to qualify at the College of Surgeons, he was talking to his fellow student, Sir Joseph Fayrer, and wondering what he should do to meet the imperative necessity for earning his bread. On Fayrer's advice, he applied to Sir William Burnett, at that time Director-General of the Medical Department of the Royal Navy, for an appointment. Within a couple of months he was, after passing an examination, entered on the books of Nelson's old ship, the *Victory*, for duty at Haslar Hospital. At Haslar Huxley had among his messmates the late Sir Andrew Clark—whom he speaks of as "my kindest of doctors"—and two future Directors-General of the Medical Service of the Navy, Sir Alexander Armstrong and Sir John Watt Reid.

When he had been there seven months he was appointed to the *Rattlesnake*, Captain Owen Stanley (a brother of Dean Stanley). On the *Rattlesnake*, which was commissioned for a survey of New Guinea, the Lousiade Archipelago, and the Barrier Reef of Australia, he spent the greater part of the years

1846-1850, learning valuable lessons as to the realities of life, and using to the full the opportunities for scientific work the cruise afforded. During his four years of absence from England he sent home many communications to the Linnean Society, "with the same result as that obtained by Noah when he sent the raven out of his ark." Tiring of this unprofitable amusement, he in 1849 sent a more elaborate paper to the Royal Society, which on his return to England in 1850 he found had been published. The next three years were occupied by a battle with the Admiralty, which, instead of contributing, as it had partly pledged itself to do, to the expense of publishing his scientific work, at last ordered him to join a ship. Huxley thereupon threw up his commission, and looked about for a professorship of physiology or comparative anatomy. Among other unsuccessful attempts he mentions that Tyndall and he were candidates at the same time for the Chair of Physics and Natural History respectively in the University of Toronto; that seat of learning, however, would have none of them. At last in 1854, on the translation of Edward Forbes to Edinburgh, Sir Henry de la Beche, the Director-General of the Geological Survey, offered him the post of Paleontologist and Professor of Natural History in the Royal School of Mines vacated by Forbes. He refused the former point blank, and accepted the latter only provisionally, telling Sir Henry that he did not care for fossils, and that he should give up natural history as soon as he could get a physiological post. "But," he adds, "I held the office for thirty-one years, and a large part of my work has been paleontological." In the same year he was appointed Fullerian Professor of Physiology in the Royal Institution, and Examiner in Physiology and Comparative Anatomy in the University of London. In 1858 he was Croonian Lecturer to the Royal Society, taking for his subject "The Theory of the Vertebrate Skull." In 1863 he became Professor of Comparative Anatomy at the Royal College of Surgeons; this post he continued to hold till 1869. He was elected President of the Geological Society in 1869, and of the Ethnological Society in 1870. In the latter year he was President of the British Association. Two or three years later he was chosen Lord Rector of Aberdeen, in which capacity he delivered an address on Universities, Actual and Ideal, on February 27th, 1874. In 1875-76 he acted as substitute in the Chair of Natural History at Edinburgh for Professor Wyville Thompson, who was on board the *Challenger* on its famous voyage of scientific exploration.

Huxley was elected a Fellow of the Royal Society in 1851. In 1873 he was appointed its Secretary, and in 1883 he became its President in succession to Mr. Spottiswoode. The latter post he resigned, together with all his other public appointments, in 1885 on account of failing health. Moreover, he had reached the age at which he used jokingly to say that scientific men should be "poleaxed."

It would be tedious to enumerate all the honours of which he was the recipient. He was a corresponding member of most of the leading scientific societies in Europe and America; the Royal College of Surgeons (of which he became a Member in 1862); elected him a Fellow in 1884; and honorary degrees were conferred upon him by the Universities of Oxford, Cambridge, Dublin, Edinburgh, Würzburg, and Breslau. The Royal Society awarded him its medal in 1862, and the Geological Society gave him the Wollaston Medal in 1876. He was a trustee of the British Museum, and a member of the Senate of the University of London. In 1892 he was sworn of the Privy Council, a mark of distinction which is still unique as far as scientific men are concerned.

Huxley's work was by no means confined to scientific research and teaching. In 1870 he was elected a member of the first London School Board, and he took a very active part in its proceedings till his resignation in 1872. In 1881 he was appointed Inspector of Salmon Fisheries, and continued to discharge the duties of that post till ill-health compelled him to retire in 1885. He served on a number of Royal Commissions—on Vivisection, Contagious Diseases, Scottish Universities, Fisheries, etc. His last public act was when, in introducing the deputation to Lord Rosebery on the subject of the proposed new University for London, on January 22nd, he presented the case of the supporters of the Gresham scheme in a speech of great brilliancy and power.

HIS LITERARY OUTPUT.

Space will not allow us to give anything like a full bibliography of Huxley's writings. His first paper, which, as already said appeared in the *Medical Gazette* in 1845, contained a description of "Huxley's layer" in the human hair. In 1849 the Royal Society published his paper on the Anatomy and Affinities of the Medusa, which had been communicated to it on his behalf by the then Bishop of Norwich (the father of Captain Stanley) on June 21st, 1849. In 1859 appeared his great work on the *Oceanic Hydrozoa*, which he had vainly tried to get the Admiralty to help in publishing. "My Lords," however, did nothing for him beyond expressing a gracious hope (which made no encroachment on the Navy Vote) that the work would be creditable to himself and to the nation.

At the meeting of the British Association at Oxford in 1860 he strenuously defended the doctrine of evolution against Bishop Samuel Wilberforce and other clerical assailants; a summary of this memorable debate is given in his *Evidence as to Man's Place in Nature*, published in 1863. In 1864 he published *Lectures on Comparative Anatomy*. In 1866 appeared his *Lessons in Elementary Physiology*, which has run through numerous editions, and still holds its place as the best introduction to the subject in the English language. Among his other works may be mentioned *Introduction to the Classification of Animals* (1869); *Lay Sermons and Addresses* (1870); *Anatomy of Vertebrate Animals* (1871); *Critiques and Addresses* (1873); *American Addresses* (1877); *Physiography* (1877); *Anatomy of Invertebrate Animals* (1877); *The Crayfish: an Introduction to Zoology* (1879); *Hume* (1879); *Introductory to Macmillan's series of scientific primers* (1880); *Science and Culture* (1889); *The Rede Lecture on the Origin of the Existing Forms of Animal Life: Construction or Evolution* (1883); *Controverted Questions* (1889); *Evolution and Ethics*, delivered as the Romanes Lecture at Oxford in 1889, besides numerous essays which have not yet been collected into book form. His last work was a criticism of Mr. Balfour's *Foundations of Belief*, the first part of which appeared in the *Nineteenth Century* of March. Huxley was taken ill immediately after writing this paper, of which we believe he was unable to correct the proofs. He was never afterwards able to do any literary work.

In all Huxley's writings the literary quality is of the best; his style in its incisiveness, strength, directness, and lucidity, being without an equal in scientific literature. Medical writers might with great advantage to themselves and unspeakable comfort to their readers take Huxley as a model. His mastery of style did not, like Dogberry's reading and writing, come to him by nature; his secret was that no sentence was ever allowed to go out of his hands until it had been made as perfect as possible, and he has left it on record that he thought nothing of writing a page two or three times over if by so doing he could arrive at a clearer expression of his meaning.

PERSONAL REMINISCENCES.

We are indebted to Sir Joseph Fayrer, a life-long friend of Professor Huxley, for the following note on his life and character:

"It was with profound grief that I heard of the death of my old and much respected friend, T. H. Huxley. The loss of the foremost biologist of this or any other country will be universally deplored, for he has for many years had a predominant influence on the progress of biological science and the expansion of scientific teaching which was not surpassed by even that of his friends, Darwin and Tyndall, and has contributed beyond all others to the advancement of natural knowledge and the promotion of the scientific methods of investigation of the problems of life. To this end, indeed, the whole strength of his surpassing intellect was steadfastly, through good and evil report, devoted, and the results have been recorded in language so incisive and convincing as to leave on all who have followed his teaching the impression of incontrovertible truth, and the conviction that in this department of knowledge he was *maestro di color che sanno*. I have always felt it to be a great privilege to have known him so well during early life. The friendship and affection in which I held him never diminished, though after his departure in 1846 I had no opportunity of seeing him again until my return from India in 1873, when I had the gratification of finding that on his part the feeling was unchanged, whilst on mine it was enhanced by the admiration with which

I regarded his great natural powers and the unwearied labour in scientific research which had raised him to the pre-eminent position he has since occupied.

"We were fellow-students from 1844 until he joined the Navy in 1846, and it was during that time that I learnt to recognise his great intellectual power and the keen interest he took in the physiological lessons of Wharton Jones and other teachers. It was not surprising that he took honours at the London University, and it was with a feeling of confidence that I looked forward to a distinguished career for him when he departed with Captain Owen Stanley in the *Rattlesnake* on his scientific mission.

"That he entered the naval service I have always felt proud to think was due to my persuasion, for after consultation one day I urged him to apply to the Director-General of the Navy. He did so, and the result was an appointment to *Master*, and subsequently to the *Rattlesnake*. Doubtless had he selected any other career the result would have been the same, but as some of his earliest contributions to science arose out of the expedition to the South Seas, one cannot but regard that as having in some degree determined the course and direction of his future work.

"To incite veracity of thought and action, to subordinate to it reasonable or unreasonable ambition for scientific fame, to develop and organise true scientific education, and to combat whatever might oppose it, were his aspirations, and that by which he hoped to be remembered by posterity. To quote his own words: 'I should not count these things as marks of success if I could not hope that I had somewhat helped that movement of opinion which has been called the New Reformation.'

"But he will be remembered not only as a great original thinker, investigator, and promoter of biological science, but as a man of the highest principle and unswerving devotion to truth, a genial and charming friend, a keen but courteous controversialist, and one who illuminated all he said or did with the brightness of a remarkable personality, and a goodness of heart that endeared him to all who knew him and now lament his loss."

On Thursday, July 4th, the remains of Professor Huxley were interred in the cemetery at Finchley, where two of his children are buried.

THE LATE DR. WILHELM MEYER.

Concerning Dr. WILHELM MEYER, of Copenhagen, whose death was announced in the *BRITISH MEDICAL JOURNAL* of June 22nd, Mr. Cresswell Baber writes: I cannot allow the death of my friend, Dr. Wilhelm Meyer, of Copenhagen, as recorded in your columns, to pass without asking you to allow me to render a short tribute to his skill as an observer and his worth as a friend. His well-known work on *Adenoid Vegetations of the Nasopharynx* is so full and careful that, except in regard to treatment, scarcely anything essential has been added since its publication in 1870. When, in 1874, I had the good fortune to make Dr. Meyer's acquaintance on a visit to Copenhagen, I had the opportunity of seeing some of his original cases, and was impressed with the keen interest he took in the subject. At that time he was engaged in general practice, as well as that of laryngology and otology, and, I believe, continued to be so. I well remember that in response to a question as to which he preferred, his reply was "that his heart was in his general practice; his head in his special work." That his interest in the subject of adenoids continued unabated is shown by a communication received by the writer only a few weeks before his death, in which he mentioned that he was occupied with an inquiry about the distribution of adenoid vegetations in different countries and races. Dr. Meyer made other contributions to medical literature, but it is with the subject of adenoid vegetations that his name will be inseparably connected.

Another medical practitioner who has fallen a victim to professional duty is Dr. ALEXANDER JELISSEFF, who died recently in St. Petersburg at the age of 46, of diphtheria, contracted from a child whom he had been attending. Dr. Jelisseff was well known as an African explorer, and was the author of a book entitled *My Journey to the Soudan*, in which he gives an account of expeditions made by him in 1892 and 1894.

BRITISH MEDICAL ASSOCIATION. SUBSCRIPTIONS FOR 1895.

Subscriptions to the Association for 1895 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office Orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, JULY 6th, 1895.

DOUBTFUL DIAGNOSIS AND EARLY NOTIFICATION OF INFECTIOUS DISEASES.

IN view of the recent decision in the case of *Mason v. Madden*, to which we have already alluded on more than one occasion, it is desirable to draw the attention of the public, as well as of the profession, to the extreme danger both to the community and to patients suffering from infectious diseases which will necessarily follow that verdict if it be not reversed.

The legal teaching of that verdict seems to be that so long as there is the slightest loophole for doubt as to the nature of a case it shall not be notified. Should a doubtful case turn out to be small-pox, or scarlet fever, or some other infectious disease, if the medical man has been careful that acts and language should reflect the doubt which he felt, it will be easy to bring evidence to show that, however suspicious it might look, the symptoms were not so positive as to justify him in certifying its infectious nature. Moreover, even if an action for failure to notify went against him, the worst that could happen would be a £5 penalty; whereas if, in endeavouring to do his duty under the Notification Act by notifying in an early stage, he should make the slightest slip, he would be liable to be cast in an unknown and absolutely unlimited amount of "damages." Under such circumstances the Notification Acts would become a farce; no man could safely notify until the case was plain, which in the case of small-pox would in many cases not be until it had declared its nature by spreading to those around.

That this is not an exaggerated view of the situation is clear from the records published by the Metropolitan Asylums Board. So great has been the difficulty of diagnosis in the early stages of small-pox, especially in those cases which are modified almost out of recognition by previous vaccination, that out of 1,263 cases certified as small-pox, and removed to the wharves as such, 155, or 12.2 per cent., were found, in the opinion of the managers' medical officers, not to be suffering from that disease. This must not be taken as betokening carelessness, but simply as showing the great difficulties which stand in the way of accurate exact diagnosis in regard to a disease which, in any case, must be of rare occurrence in the practice of medical men, and it may be taken that this is an average of error which must somehow or other be provided for in the administration of the Notification Act.

We do not say that there may not have been carelessness

here and there, but when we find in how large a proportion of cases mistakes are made year after year by practitioners who on the average are very careful men, and in this matter are certainly acting with a full sense of responsibility upon them, we may be perfectly sure that the problem put to them is a very difficult one, and one not always capable of an exact solution. Even with a specialist who passes his life examining these cases, who has power to detain them in case of doubt, and is provided with wards in which to observe their progress until the doubt is cleared up, even with such opportunities as this mistakes are sometimes made. Of the cases brought to the Wharfe in 1894, 61 were returned home at once as not suffering from small-pox, but 147 were retained for further observation, of whom 50 ultimately turned out to be suffering from small-pox, and 97 from other disorders. But even after all this careful sifting of the cases by a medical specialist of large experience, with every appliance, and with opportunity for calling to his aid that great clearer of all mysteries—time—mistakes were made, and 10 patients not suffering from small-pox ran the gauntlet and were admitted to the ships. This should be taken note of by judges and magistrates.

There always must be a certain average of mistakes in a matter like this, in which the most expert occasionally fail, and, however complimentary to science it may seem, it is an absolute misrepresentation of the facts to suggest that an error in such a matter shows either ignorance or negligence. The danger to the public which will result if this unfortunate verdict, to which we have alluded, be not reversed can only be understood by a recognition of the enormous services done to London by the Ambulance Committee of the Asylums Board. Again and again it has happened that by obtaining early information of the existence of small-pox they have been able to nip in the bud what otherwise might have been a great epidemic; but their early action has hinged on a liberal interpretation of the Notification Act and an understanding by medical men that if they act honestly in the matter they will be held free from blame.

All these benefits will be thrown away if once it is decided that a doctor cannot safely notify until he can be actually positive of the nature of the disease, and able to defend his opinion in a court of law. It is not a matter of small-pox alone. The diagnosis of either scarlet fever or diphtheria is equally full of pitfalls. During last year 320 mistakes were made in the diagnosis of scarlet fever, and 348 in regard to the much smaller number of cases of diphtheria. In fact in regard to the latter disease notification is utterly hopeless if strict certainty is to be insisted on, for there are, if one may so say, two diphtherias, according as one accepts the clinical or the bacteriological test, while the Notification Act says nothing as to which definition is to be followed, and no man could know which would be accepted by a magistrate. There is, however, another aspect of the question. Not only does anything which delays notification impede early isolation in hospital, and thus tend to spread disease among the healthy, but it inflicts much injury upon the sick themselves, by putting off the day of their removal to a period in their illness when the transit from home to hospital is attended with much greater danger than if it had been undertaken at an earlier stage.

In regard to this, Dr. Goodall, of the Eastern Hospital,

is most emphatic. He says: "With respect to enteric fever I have to observe that this disease is, especially in its early stages, often very difficult to diagnose with certainty. It is also most important that if a patient suspected to be suffering from enteric fever is on account of his surroundings to be removed to a hospital, he should be removed as early as possible, without waiting for several days until an absolutely certain opinion as to the nature of the disease can be given. For in many cases absolutely certain symptoms are only observed at a period of the disease when even a most careful removal is fraught with the gravest risk to the patient's life." This puts the thing in a nutshell—to wait for certainty before notifying makes removal dangerous to the life of the patient, and deprives the community of the very benefit for the sake of which sanitary authorities are so freely spending money on isolation hospitals; yet that is just what must be done if this most unfortunate verdict in the case of Mason v. Hadden is allowed to stand.

THE BEDFORD SCANDALS.

THE records of workhouse scandals are many and various, and we fear that the state of things to which we have had occasion already to call attention in connection with the management of the Bedford Workhouse and Workhouse Infirmary is likely to obtain an unenviable notoriety. It is the old story. In July, 1894, there arose two troubles. A nurse who had given the utmost satisfaction, and against whom no charge had been made, was practically turned out because she belonged to the Workhouse Infirmary Nursing Association, which, as all our readers know, is a very useful body under the presidency of the Duchess of Teck. About the same time Mrs. Stanley Lane-Poole and her friends, who had been doing their best to bring help and kindness into the workhouse, and who were at that very moment proposing to organise a ladies' visiting committee, found the door practically shut in their faces by the master for no reason whatever, except, possibly, that that official considered the free exercise of his authority to be endangered. This state of things led to heated discussions on the Board, and formed apparently the staple of the arguments upon which the new election of guardians was fought. Nothing was more plain in the course of these discussions than that the whole question turned upon the fact that everybody, from the Board of Guardians down to the lowest menial in the house, was practically under the thumb of the master. We have never suggested, and we do not suggest, that it is not perfectly proper that the master of such an establishment should have all the authority which is necessary for discipline: but it is obvious to everyone that with a sleepy Board of Guardians, and with lady visitors practically excluded, and nurses of any independence dismissed, a master of this sort may easily become an autocrat practically uncontrollable.

At Bedford certain specific complaints against the master were, however, put into shape, and one section of the Board insisted upon having a committee of inquiry. This was refused by the old Board, and was granted by the new one. A large quantity of evidence was taken, but it was taken *in camera*: and, although that was many weeks ago, the shorthand note does not appear to have even yet been fairly submitted to the judgment of the whole Board. The evidence was, however, privately submitted to the Local Government

Board, who thought the charges sufficiently important to call upon the master for an explanation. The inspector for the district, Mr. Augustus W. Peel, is well understood to be no particular friend of reform, and presumably upon his advice the Local Government Board, although they reprimanded the master, considered that the evidence did not show "sufficient cause" for the holding of a Local Government inquiry. The independent report furnished to us by our own Commissioner as to the administration of the establishment, especially as regards the nursing of the sick, the care of the infants, the appointments of the infirmary, and the sanitary arrangements, convinces us that the management is defective. We are not surprised that those responsible for it are not anxious to have in the house such an independent and skilled observer as the nurse they dismissed appears to have been. Apart from the questions referring to the treatment of the inmates, the charges affecting the officers appear to resolve themselves into this—that sundry irregularities are said to have been committed in providing entertainment for the master's guests, and otherwise promoting their comforts and luxuries in ways that were improper. For all these charges the master of course had his answer. So far as we gather, he admitted many of the irregularities, and endeavoured to minimise and explain them away. That the Local Government Board did not altogether accept his view appears from their words of censure. In the end the master wrote a formal and, as it seems to us, in effect an impertinent, letter to the Board of Guardians expressing his regret that in some of the respects mentioned his past action had been "contrary to the views of the Local Government Board," and assuring the guardians in future that he would act strictly in accordance therewith. The same letter contained a threat of a libel action against the persons who had accused him of "tyrannous oppression" within the house, as to which it does not appear that any serious inquiry has yet been held at all. We do not know whether this threatened action is now pending, but in any case we do not propose to say anything about that aspect of the situation, as to which we have no facts before us. A workhouse master may be practically the autocrat of the establishment, and may be also a very humane and kindly man. It is the absence of efficient control which is the scandal. The occurrence of particular irregularities is only a symptom of the disease, and the object of those who criticise such a state of things is, or ought to be, not to vilify the master, but to reform the system. The present result appears to be that the Board by a small majority have resolved to support the master, and go on in the old way. The members who dissent from this course contend, with very good reason, that the investigation, so far from being finished, is barely begun, and that the evidence taken before them was merely such as they were in a position to gather together, in the face of the constant hostility of the master, who appears to be backed up by the clerk and, in fact, by the whole of the "old gang," and that the purpose and proper effect of their private and partial investigation was merely to lead up to a Local Government inquiry, which should be formally and regularly carried out.

We do not hesitate to say that it would be quite intolerable if the matter were to rest here. The Board of Guardians ought not to stop until they have forced the Local

Government Board to have the matter sifted to the bottom; and we venture to say that for that purpose it is not only necessary that an inquiry should be held, but it is also necessary that that inquiry should not be held by the gentleman who, as inspector for the district, has already to some extent taken sides in the matter. Few things about the Local Government Board arrangements are less satisfactory than their curious practice of sending the district inspector to act as a *quasi*-judge, where scandals are alleged to have arisen in institutions for which he is himself largely responsible. In this and in many other respects Bedford is a test case. It remains to be seen whether the new head of the Department will permit such a matter to be hushed up, even if a majority of the guardians are willing to consider it as terminated by a "conclusion in which nothing is concluded."

HUMAN AND VETERINARY MEDICINE.

It is a matter of no small interest to observe how, from the earliest times, observation of the ailments of animals and the knowledge gained from the more or less experimental treatment of their diseases has influenced the progress of medicine proper as applied to man. Malm,¹ in a graduation thesis, discourses upon the relationship which has existed between veterinary and human medicine from the days of antiquity to the present time. The first historical references to the healing art in ancient times have to do with veterinary medicine. There is a tradition of a Greek shepherd, Melampus, who is said to have lived centuries before the siege of Troy, that on account of his knowledge of diseases of animals he was called in to see a King's daughter, whom he cured of a maniacal condition by means of the *Helleborus albus*. The result, according to the legend, showed the correctness of Melampus's deductions as to the similarity between the diseases of man and animals, for he had found this plant useful for apparently similar conditions in his sheep. In course of time *Æsculapius* appears, and for some centuries after him the veterinary art seems to have been neglected, until it was revived again by Hippocrates and Aristotle, both of whom derived their knowledge of human medicine from the study of animals.

After the commencement of the Christian era and up to the fifth century veterinary medicine was very flourishing, and put human medicine completely into the shade. To this result, the very opposite of what might have been expected, several causes contributed. Knowledge of veterinary medicine was improved partly owing to the appearance of such men as Columella (40 A.D.), who was the first to place veterinary medicine upon a scientific basis, and at a later period Apsyrus (320 A.D.), who wrote a description of nearly every known disease in animals. Another cause of the advance of veterinary art at this time was the great military luxury prevalent in the Greco-Roman Empire, and especially at the Byzantine court, where, for instance, the office of chief master of the horses was one of the greatest honours conferred. Human medicine, on the other hand, had begun to be neglected even before the Christian era, and, until Omar gave them civic rights, the physicians were either slaves or freedmen. After the time of Christ it sank still lower, and human medicine

spoke with great contempt of the practice of medicine. This inferiority continued until the twelfth century, and was probably caused in part by the influence of powerful ecclesiastical bodies which so often showed themselves hostile to scientific research and freedom of thought, but it was no doubt also largely due to the military spirit then so prevalent and to the growth of the feudal system, which gave small consideration to weakly men but thought everything of horses, which were the special appanage of the knightly classes, to whom, in fact, they gave their proud pre-eminence.

This long period did not produce any scientific writings of value. Human medicine during this time appears to have departed from the road of true research, and to have neglected the teachings of experience; it was completely dominated by mysticism and superstition.

With the establishment of the universities, however (twelfth to thirteenth century), human medicine made rapid progress. In the beginning of the thirteenth century Luzzi, in Bologna, began to make *post-mortem* examinations of human bodies, but it was not until the beginning of the sixteenth century that the real study of human and animal anatomy began. During this century Ruini wrote a book on the anatomy of the horse. It is interesting to note that it was this work which was the origin of the Italian opinion that the honour of having discovered the circulation of the blood should be given to Ruini. It is true, indeed, that this author understood the pulmonary circulation, but he had erroneous views about the function of the veins. It can scarcely be denied that Harvey knew Ruini's work, but most probably in this case, as with most human discoveries, the work was prepared by many, the discovery made by one. This work of Ruini's remained for long the only important contribution to veterinary science. In fact, the scale had turned. The knowledge of human medicine was gradually settling itself on a firmer basis, while by the time of the appearance of the great cattle plague, which was imported from Russia, and raged throughout Europe in the beginning of the seventeenth century, the veterinary art had sunk almost entirely into the hands of the farriers. There was thus no one to meet the emergency, and the various Governments were obliged to turn to the practitioners of human medicine for help. This severe warning was the chief cause of the establishment of veterinary schools, the first of which was founded by a French advocate, Bourgelat, in 1762 in Lyons. But what was taught in these schools for a long time was chiefly human medicine applied to animals. Several countries possessed no such schools, but the subject was included in their courses by a few members of the medical faculty at the universities; and thus arose a praiseworthy effort to create a true comparative pathology. The realisation of this effort only became possible later by the advancement of experimental pathology, of which bacteriology has recently become a prominent department.

It is interesting to note the varying progress of the two great branches of medicine. Sometimes the veterinary, sometimes the human, has taken the lead, but whatever has been learned in the one has been of service to the other. While physiology shows the general similarity of the action of protoplasm, the basis of living matter, whether in animals or in man, we may fairly believe that those interferences with life processes which we call disease are analogous in both, and we can readily recognise the honourable part taken

¹ Nord. Medicin. 35, 1895, 1896, 1897, 1898, 1899.

by the veterinary art in the gradual evolution of that science of medicine which is now being applied for the equal benefit both of animals and man.

The honour of knighthood was conferred on Mr. Thornley Stoker, President of the Royal College of Surgeons in Ireland, and on Dr. Christopher Nixon, Senior Physician to the Mater Misericordiae Hospital, by the Lord-Lieutenant of Ireland (Lord Houghton) on July 4th.

At a meeting of the Court of the University of Wales held on July 2nd at the University of London, Dr. Isambard Owen, Senior Deputy Chancellor, in the chair, the Prince of Wales was unanimously elected Chancellor of the University of Wales. The first Chancellor of the University was the late Lord Aberdare.

By the will of the late Mr. Peter Waddell, Leith, which has been recorded in the books of Council and Session, it is ordained that the residue of the property should be paid in equal shares to the Langmore Hospital for Incurables, Edinburgh, to the Royal Edinburgh Blind Asylum and School, to the Edinburgh Royal Infirmary, and to the Leith Hospital and Humane Society. It is expected that this residue may amount to £200,000—that is, £50,000 to each of the four charities named.

ST. ANDREWS AND DUNDEE.

THE St. Andrews University Bill, the object of which was to disjoin Dundee University College from the University of St. Andrews, has been dropped. The two Colleges had been affiliated by an order of the Scottish Universities Commissioners appointed under the Act of 1889. It was contended that this affiliation was *ultra vires* on the part of the Commissioners.

THE MECCAN PILGRIMAGE.

THE Meccan pilgrims are now returning at a critical and momentous period. We learn by letter from an authoritative source that up to June 18th seven ships with about 6,000 pilgrims had arrived at Tor, and on two of them there were cases of cholera followed by death. At the time the despatch boat left Tor on June 19th only one of the cases had been confirmed by bacteriological examination. All the vessels arriving at Tor have it stated on their bills of health that there is a good deal of cholera at Mecca. Fifteen days' quarantine is imposed on all pilgrim ships arriving at Tor from Djeddah, and all passing the Canal will be sent through in quarantine. The Egyptian pilgrims, after passing their fifteen days in one encampment at Tor, will be required to undergo another period of three days' observation at that place in a new camp before they will be allowed to land at Suez.

HYGIENIC DAIRY FOR EDINBURGH.

At a meeting held in Edinburgh last week it was arranged to establish a hygienic dairy company. Dr. Foulis, who presided, referred to the report published as to the insanitary condition of Edinburgh byres, and found in this the most powerful argument for the scheme they had met to inaugurate. He referred to the great susceptibility of milk to evil influences from infectious and contagious diseases, whether these latter existed in the animals or in the human beings working amongst them; to the unsatisfactory state of notification of disease; and to the want of fit supervision of persons supplying milk from outside the city. He urged the necessity for preventive measures, and the importance of constant and skilled medical supervision of all human beings

and animals located on the proposed hygienic dairy farm. Thus there would be guaranteed to the inhabitants of Edinburgh a supply of milk uncontaminated in any way by the germs of bovine or human disease. Necessarily the water supply and sanitation of the new dairy farm would have to be beyond suspicion. A limited liability company is to be formed, with a capital of £20,000, in £1 shares. The scheme is being taken up, not from a speculative point of view, but from a philanthropic aspect, although care would be taken that the scheme was launched on a sound financial basis.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual general meeting of this Society was held at 42, Strand, on June 23th. Mr. Joseph Smith was elected President for the year, Mr. George Brown Hon. Treasurer, and Mr. W. G. Dickinson (Southfields, S.W.) Hon. Secretary. The Secretary reported the correspondence between the Committee of the Society and the Home Office in connection with the recent amendment of the by-laws of the College, the result of which met with the approval of the meeting. The following resolution was proposed by Mr. Nelson Hardy, seconded by Dr. Thos. Martin, and carried unanimously: "That this meeting is of opinion that the time has now come when active steps should be taken to secure for Members of the Royal College of Surgeons of England their due share in its management, in accordance with the request of nearly 5,000 Members, contained in the petition to the Privy Council in the year 1887." The Hon. Secretary will be glad to receive the names of any Members of the College wishing to join the Society. The annual subscription is half-a-crown.

MEDICAL OFFICER OF HEALTH FOR LAMBETH.

DR. JOSEPH PRIESTLEY, B.A., M.D., D.P.H., has been elected to the post of Medical Officer of Health for Lambeth by a very large majority. Dr. Priestley is the well known Medical Officer of Health at Leicester, and during the small-pox epidemic there was the centre of many attacks and abuse at the hands of the antivaccinationists, who did their utmost to force his hands. Dr. Priestley, however, stood firm to his opinions, and by so doing scored all round, whilst his *Reports on the Epidemic of Small-Pox* have had a widespread circulation and renown. Dr. Priestley has been three years at Leicester, and was formerly Assistant Medical Officer of Health to the Vestry of Camberwell, so that he has had a wide experience in administrative public health work, and has written some important papers and reports on various public health questions.

SIR H. D. LITTLEJOHN.

THE many friends of Dr. Littlejohn in all parts of the world will join in congratulations on the honour which Her Majesty has been pleased to confer upon him on the advice of Lord Rosebery. Dr. Littlejohn took the degree of M.D. at the University of Edinburgh in 1847: in the same year (as was then the custom) he became a Licentiate of the Royal College of Surgeons of Edinburgh, and in 1844 a Fellow of the same College. It was in connection with the famous Pritchard poisoning case, that Dr. Littlejohn first came to the front as a recognised toxicologist. Since that time, whether as medical officer of health and police surgeon for the city of Edinburgh, as officer of health to the Board of Supervision (now the Local Government Board) for Scotland, or as a medical expert in Crown cases (especially in poisoning), he has been prominently before the public, and has now a deservedly high reputation as medical jurist, toxicologist, and authority on matters of public health. Not only does Edinburgh owe much to him, but Scotland. It is difficult to realise the enormous improvement in the public health affairs of Edinburgh during his long term of office.

Typhus fever is no longer an appreciable quantity, and the rate of mortality has gone down to a very low figure. Dr. Littlejohn is lecturer in the Extramural School on medical jurisprudence and public health. He was an examiner in the same subject in the University of Edinburgh some years ago, and is now an examiner for the Royal Colleges of Surgeons and Physicians of Edinburgh and the University of St. Andrews. He was formerly President of the Royal College of Surgeons of Edinburgh and of the Medico-Chirurgical Society. When the British Institute of Public Health held its Congress in Edinburgh, in July, 1893, he was called to the presidential chair, which he occupied most admirably. On August 1st of that year the University of Edinburgh conferred upon him the honorary degree of LL.D. Personally Dr. Littlejohn is the most genial of men—a favourite with everybody. He finds relief from the severer duties of his profession by the cultivation of art. He has long been known as an admirer and judge of Landseer engravings, of which he has a large and valuable collection.

PATHOLOGY AT TRINITY COLLEGE, DUBLIN.

THE Board of Trinity College, Dublin, has appointed Dr. A. O. O'Sullivan to the new Lectureship on Pathology in the School of Physic. Dr. O'Sullivan is one of the most distinguished Fellows of Trinity. After taking his medical degree he proceeded to Vienna, where he studied for a considerable time, and on his return to Dublin he was appointed Pathologist to the Richmond, Whitworth, and Hardwicke Hospitals.

SHORT-TIME APPOINTMENTS IN THE PUBLIC HEALTH SERVICE.

WE find in the *Bradford Observer* of June 26th the following typical instance of the "fixity of tenure" enjoyed by medical officers of health outside London: "The period for which Dr. J. J. Rutherford had been appointed medical officer of health being about to expire, the Council proceeded to the election of a successor. The applicants were Dr. Rutherford, Dr. Foster, and Dr. Eames. It was resolved to decide the matter by a ballot vote, and, on the ballot papers being counted, it was found that 8 members had voted for Dr. Foster, 5 for Dr. Rutherford, and 2 for Dr. Eames. It was then formally proposed and adopted without dissent that Dr. Foster be appointed medical officer." This is not the way in which medical appointments ought to be held or terminated.

MEDICAL PRACTITIONERS AND PATIENTS' FRIENDS.

THE following case, which recently occurred in Belfast, illustrates the difficulties and even dangers which surround the practice of the healing art. On May 4th the wife of a carpenter was delivered of a child, her medical attendant being Dr. Cathcart. After delivery a tumour was discovered, and Dr. Smiley, a neighbouring practitioner, was called in consultation. As the case presented exceptional difficulties, Dr. John Campbell, surgeon to the Samaritan Hospital, was summoned. The diagnosis seemed to lie between extruterine foetation and a tumour, and after full examination the opinion of the doctors inclined to the latter view. The friends of the patient, however, became possessed with the idea that a second child was present. The propriety of removing the woman to hospital and having an operation performed was strongly urged by the medical men, but the husband positively refused to consent. The next evening, however, the patient was taken to the Samaritan Hospital, on the understanding that no operation would be performed without consent. On the third day after admission the woman's condition became decidedly worse, and Dr. Campbell arranged a consultation with Dr. Cathcart and Dr. Smiley, with the view of further pressing the necessity of operation upon the husband. When the doctors met, however, it was evident that the time for operation was past, and the patient died soon

afterwards. The death certificate stated that the cause of death was "Abdominal tumour and peritonitis." Nevertheless the friends of the patient persisted that a second child had been left in the womb. Finally, an order was sent down from Dublin Castle for the exhumation of the body and for the holding of an inquest. Dr. A. V. Macan, of Dublin, was instructed to make the *post-mortem* examination, in which he was assisted by Dr. Brice Smyth of Belfast, and Dr. Duff of Aghaloe. The inquest was held on June 25th, at Soldierstown, near Moira, where the deceased had been buried, the presiding coroner being Dr. Mussen, J.P., Coroner for South Antrim. The necropsy showed the presence of an ovarian tumour with a twisted pedicle and a rupture, and that this was the cause of death was deposed to by the three doctors who had made the *post-mortem* examination. Some peritonitis was also found. Evidence was given by Dr. Campbell, Dr. Smiley, Dr. Cathcart, and Dr. Darling, of Lurgan, who had also seen the patient; and, after a full investigation, the following verdict was returned by the jury—namely, "That Margaret Robinson died on Saturday, May 11th, 1895, at the Samaritan Hospital, Lisburn Road, Belfast, from natural causes—namely, the bursting of an ovarian tumour. The jury are of opinion that every care and attention was given to the deceased by the medical men who attended her." The medical men who have been subjected to so much annoyance have the heartiest sympathy of their brethren in Belfast and Ulster.

EPSOM COLLEGE.

THE Prince of Wales, who will be accompanied by the Princess of Wales, will lay the foundation stone of the new Lower School at Epsom College, at 3 p.m., on Monday next, July 8th, and not on Tuesday as previously arranged. Tickets of admission to the ceremony, which will be issued according to priority of application, can be obtained from the Secretary (37, Soho Square) or from the Bursar at the College. A special train will leave Victoria Station at 1 p.m., and will return from the Downs Station at 5 p.m.

WOOLSORTERS' DISEASE.

WOOLSORTERS' disease was the subject of a short conversation in the Factories Bill Committee on June 27th. Clause 26 gives the Home Secretary the power to prohibit or restrict employment for all or any classes of workers in any trade certified to be dangerous or injurious to health. Clause 27 provides that notice of certain industrial diseases, including arsenical poisoning and anthrax, shall be sent by every medical practitioner to the chief inspector. Upon this latter clause Mr. Byles, M.P., said that he had received strong communications on the subject both from the National Union of Woollsorters and from eminent medical men who had been specially concerned in cases of this kind. He asked Mr. Asquith whether steps would be taken under Clause 26 to provide regulations whereby those engaged in the sorting of foreign wools should be protected from danger to their health by the adoption of a code somewhat similar to that provided by the Bradford Corporation. Mr. Asquith replied that he hoped that after sufficient inquiry some such code of regulations would be imposed. He was thoroughly aware of the injurious nature of the occupation referred to, and had it fully in mind in framing the clauses under discussion.

NOTIFICATION DIFFICULTIES.

AS far as we can make out from a long account in the *Oldham Chronicle*, a case which ought never to have been brought into court has been decided in the least unsatisfactory way possible under the circumstances. A medical practitioner, Dr. Thomson, was charged with an infraction of the notification clauses of the local Act, in having failed to notify "forthwith" certain cases of enteric fever. All the patients were members of the same household. It seems

that in the early stages the diagnosis was obscure as between typhoid and influenza, and although at the end of a week a provisional diagnosis of the former was made, it was not until some days later that all doubt was removed. After the lapse of a few days more, the medical officer of health, Dr. Tattersall, heard of the cases and called at the house for the purpose of making inquiries, and met there Dr. Thomson, who confirmed the report and expressed regret for the delay which had occurred. There the matter might very well have ended, but the Sanitary Committee of the corporation, who appear to have conducted their deliberations in the presence of reporters and without much reticence, decided to press it further. They summoned Dr. Thomson to meet them, and upon his refusal advised the institution of legal proceedings against him. The case accordingly came before the borough magistrates, who held that Dr. Thomson "had not wilfully and without reasonable excuse offended against the section of the Act in question." The case was dismissed with costs. The frequent difficulty of making a positive diagnosis in the early stages of enteric fever is well known to every medical man, and there was here no allegation of intentional concealment in the particular instance, or of habitual neglect of notification by Dr. Thomson. He might perhaps have notified earlier, and it would have been well to send a guarded notification to the medical officer of health when the provisional diagnosis was made, although the law scarcely imposes that as a statutory duty. These omissions, in an isolated instance, amount to little, and were surely amply covered by the verbal explanation given to Dr. Tattersall. The refusal to attend the meeting of the committee was not unnatural, since the members had permitted themselves singular latitude of speech in their previous discussion of the matter before the reporters. If, as an editorial note in the local paper suggests, the outcome of this case is to authorise medical practitioners to delay notification indefinitely, the responsibility rests with the Sanitary Committee, who selected their battleground with little discretion. We venture to think that no such evil consequences will follow, but that the notification system will continue to work smoothly and harmoniously for the public good, in Oldham as elsewhere, and none the less satisfactorily for the rebuff which the Sanitary Committee have courted and received.

THE LEICESTER PROVIDENT DISPENSARY.

A CONSIDERABLE amount of correspondence has recently appeared in the Leicester papers in regard to the article which appeared in our columns on June 8th in regard to the Leicester Provident Dispensary. No attempt has been made to traverse our facts, or to show that this institution, which is now being so largely used by the middle classes, is not a charity, or that it is not extravagantly managed. In fact, directly attention was drawn to the sums paid in salaries, and especially to the salary of £2000 a year paid to the manager, it became evident that this was an old sore to many of the Leicester people, and was a matter regarding which many severe strictures had already been made. The correspondence has, however, served to bring into prominence the claim of the well-to-do to partake in the benefits of the dispensary; in fact one of the writers claims that Leicester has succeeded in organising the medical profession for the relief of the lower and middle classes by means of this provident dispensary. It is necessary therefore again to insist on the fact that this dispensary is a charity, that the medical men on its staff are among the largest supporters of it, by means of their semi-gratuitous scale of fees, and that well-to-do people have no right whatever to partake of its benefits. Medical men have never held back from giving their services to the poor and needy, and in offering for small and unremunerative weekly payments to attend those who are not quite so poor as to be objects of simple charity, and yet cannot pay ordinary fees; but the intrusion of well-to-do people into this semicharitable or-

ganisation entirely alters the aspects of question, and it is strange that the working classes do not see that it threatens with destruction a scheme organised for their benefit. According to the plan of a properly organised provident dispensary, the doctors live by their private practice, and give their services to the deserving poor at a very low rate: give in fact far more than they are paid for. According to the plan which the Leicester people profess to have organised, but have not; each man gets only what he pays for, that is he gets the value of 2s. 10d. a year in medical attendance. It is impossible not to see that the poor are better off according to the first scheme, and that the attempt to "organise the medical profession" on the basis of a remuneration of a little over a halfpenny a week must, if it should ever be successful, end by limiting the medical attendance on the poor to attendance of such a character as is fairly remunerated by such a payment, which is not at all what the poorer members of the working classes want, or what they have been in the habit of receiving from these institutions.

THE DOCTOR'S LIFE AND WORK.

At St. Mungo's College, on Saturday, June 29th, Dr. D. C. McVail delivered the closing address to the students in the rooms of the Medico-Chirurgical Society. He said there was no enormous difference between men engaged in the ordinary work of life and a true and genuine member of the medical profession, except that his best work was done among those from whom he could expect no reward, and sometimes not even gratitude. In that respect the medical profession resembled the Church, but its work entailed far more labour and self-sacrifice. The true doctor was an unpaid medical missionary. The merchant, the manufacturer, and the engineer were as well educated, though on different lines, as the medical man; but they differed in this, that the best of the medical work was given to the poor as though they were rich. Government payments to medical men were a mere fraction of the market price of the work that the profession had to do. Though the medical man seemed to live a public life, the nature of his duties made him probably the most solitary man in his village, carrying secrets of importance, and knowing oftentimes conditions of life and health which he must keep locked up against his most unguarded moment. His duty lay with his own conscience alone. His patients could not judge of his failures or of his triumphs. The public could not estimate his work as they could that of a clergyman or a lawyer. The doctor's work, so far as the patient was concerned, was written in water. Work of this solitary type was fraught with grave temptations and dangers to the medical man. Why should he continue to be the plodding hard-working student, watching the advancement of medicine in all its particulars if no one could judge of his excellence or otherwise? This was the reason why so many men ceased to be students when comfortably settled in practice. They found the easy, charming, and pleasing manners as acceptable to patients as sound medical skill. These men found it easy to make their way in life. There was nothing wrong with that, quite the opposite, but they were apt to make these graces and accomplishments do the work of better qualifications and hard study. It was in this way that even in the Church the art of pleasing was now made to do the work of the scholar and the brainworker. The pulpit was paralysed and religion made an affair of emotion instead of intellect, which was its only safe basis. Thus medical men were apt to become servile, a kind of superior servant to the great man, a trifle above his butler. These persons were apt to neglect those who were poor, and it was impossible for medical men to maintain the high position of the profession if they broke their connection with the poor. There the best work was done. It was done for no praise. It was there that the best of the men came out, partly because they were not concerned in pleasing the patient, and so could do what was best for him. In that work they

should not even expect gratitude for doing what they conscientiously know to be the best. Social and influential position was dearly bought if it led to the degeneration of the whole man. If the medical man wanted satisfaction in his life's work it must be because it had been done in the most absolute self-sacrifice. Success in society was not the chief end of the true physician, though it might seem so to him who was merely a student or practitioner in the art of pleasing. In an assembly of medical men it was not always presidents and vice-presidents or hospital physicians and surgeons who were necessarily the best men present in point of medical knowledge or experience or training. Professional success consisted in doing the greatest good to the greatest number of people. The future of the race was in the hands of the profession, and the work of the doctor in obscure streets, in cottages and hovels, improved the population, rendered the children healthy and strong, improved the manhood and the womanhood. There was no better work done in this country than that done in the East and South of Glasgow and London. The promise given long ago of a time to come when "the people would walk and not be weary, and run and not faint," would doubtless be attained, and in its attainment the medical profession would play the greatest part. Those listening to him would shortly have an opportunity of taking part in the work and of bringing it about. It was the poor work that would enable them to do all work well, and their work was worth doing well. From the very day on which they received diplomas they would affect not only the lives of those whom they were called upon to cure, but the lives and welfare of generations to follow. A vote of thanks was, on the motion of Mr. C. P. Legge, cordially given to Dr. McVail for his address.

CLUBS AND THEIR RESPONSIBILITIES.

THAT people who undertake to perform delicate services for others may sometimes be held liable, either criminally or civilly, for their failure to carry out their undertaking is a matter of common knowledge. The responsibility which attaches to them must constantly be present to the minds of all members of the medical profession; and reports of cases tried from time to time in the law courts show that this responsibility is a very real one. In a case tried recently in the county court at Lincoln there was an attempt to extend this liability beyond the limits hitherto fixed by our law, which if it had succeeded might have opened very wide the door for possible future claims. A friendly society contracted to supply medical attendance to its members and their families, and retained the exclusive services of a qualified medical man for the purpose, allowing him, however, to attend midwifery cases for the wives of the members, and to charge them for such attendance. One of these cases had an unsatisfactory result, and the member thereupon brought an action against the society to recover damages for the alleged negligence of the medical attendant. He was not a defendant, and the report does not say whether he had an opportunity of vindicating his professional character; but the jury found that he was negligent, and assessed damages against the society. The judge, however, held that they were not liable. The general contract to provide efficient medical attendance was fulfilled by securing the services of a fully qualified medical practitioner, against whose testimonials and general reputation nothing could be said; and that there was no contract between the society and the plaintiff to provide medical attendance in midwifery cases. In those cases the society did not direct or control the manner of treatment, and could not require their medical officer to treat at all. This decision seems right. The action was probably brought against the society as being a better mark for damages than the doctor. The midwifery fees in all probability amount to very little, though the one charged to the plaintiff sufficed to fix the legal liability. Whether the result of the case may not be on the whole beneficial to the medical profession time only can show.

Recently there have been numerous complaints that the growth of benefit societies which provide medical attendance for their members in return for small subscriptions, out of which smaller salaries are paid, has interfered with private practice. The knowledge that they have no right to compensation in cases of unskilful treatment or neglect may perhaps make some people prefer to call in and pay their own medical man; but the passion for cheapness will probably prevail in most cases. Those who will not spend their money in fees should, however, remember that when they save these, they at the same time forego the right to blame anyone if things go wrong.

THE LATE PROFESSOR HUXLEY.

THE death of Professor Huxley deprives biological science of one of the most remarkably gifted minds which has been devoted to its study, not only in this generation, but at any time in its history. Huxley was in his time an ardent and successful student of minutiae, but it is not for his achievements as an observer, admirable as those were, that he will be remembered. To quote the words of Haeckel, "More important than any of the individual discoveries contained in Huxley's numerous minor and greater researches on the most widely different animals, are the profound and truly philosophical conceptions which have guided him in his inquiries, and have enabled him always to distinguish the essential from the non-essential, and to value special empirical facts as a means chiefly of reaching general conceptions." It was as an expositor that Huxley exercised the greatest influence on his generation. Possessed of a singularly clear and logical intellect, and of a fearless rectitude of character which made him shrink only at the threshold of the unknowable, he was endowed also with the rare faculty of expressing his conclusions, and the argument upon which they were founded, in a perspicuous style which never left the reader for a moment in doubt of his meaning. Huxley had a larger share than any other man in driving the thesis of evolution into the very fibre of the mind not only of biologists of this generation, but into the popular intelligence, thereby influencing not only the development of biology, but the whole trend of scientific and even of political thought. It is hazardous to prophesy the duration of reputations nowadays, but there is no risk of the future falsifying the belief that the influence which Huxley has had on this generation will not die with it, but will continue to affect the course of scientific thought for many generations to come. We give in another column a brief account of the facts of his busy life, but his real history is written in the minds of men. He was essentially a teacher—a teacher not only of the ignorant, but a teacher of the teachers.

PHYSIOLOGY AND FICTION.

OUIDA has always professed to be a lover of animals, but in these latter days she would seem to have transferred her affections from guardsmen to dogs, birds, and other creatures which, if not much more intellectual, are a good deal more respectable from a moral point of view than her former pets. We congratulate her on the acquisition of a healthier taste; it is a symptom of literary regeneracy which makes one think it possible that she may yet come to see how grotesque a figure she cuts, flashing her little toy sword in the face of science. In the summer number of the *Illustrated London News* she has a "shocker" with the blood-curdling title of "Toxin," all about a wicked English surgeon, by name Damer, who, having saved the life of an Italian Prince (with a figure, it need hardly be said, "full of grace and strength like the form of the Greek Hermes in the Vatican"), stays on with him at Venice in peace and amity, like La Fontaine's cooks, till the beautiful Veronica Zaranegra comes on the scene, when, of course, the situation becomes one of more or less open war. The godlike Prince falls ill with what we are assured "the faculty call Boulogne sore throat"

and "the vulgar call diphtheria"; and Damer, finding him an obstacle to the conquest of the lady and her fortune, calmly helps Nature to suppress his rival by giving him a strong dose of "the venom of the toxin" on pretence of administering antitoxic serum. The story is as silly as Ouida's productions usually are, but with that we have no concern. What we do protest against is that a scoundrel like Damer should be presented as the type of a scientific surgeon. There can be no doubt as to the purpose of Ouida's story; it is an attack—feeble and futile, it is true, but most malignant in intention—on the medical profession. Damer practises vivisection in a place "where the clang of hammers and the roar of furnaces drowned the cries of animals which it was not convenient to make sphone (*sic*)"; he operates on a man "at death's door with cancer of the food and air passages," and although the patient dies under his knife, he boasts that he has solved "a doubt which has never been solved before, and never could have been without a human subject." When taxed with cruelty because of this operation, he replies that such terms as cruelty or kindness "do not enter into surgical vocabularies." This kind of thing is only an echo of the ravings of certain catchpenny newspapers, and deserves no serious notice. But when the man whom the reader is asked to accept as the representative of scientific medicine is made to justify murder on the ground that "science bade him take all the other sentient races of earth, and make them suffer as he chose and kill them as he chose," and to argue that, while "it would be what men called a crime . . . his school despises the trivial laws of men, knowing that for the wise there is no such thing as vice and no such thing as virtue," we think we have some reason to complain. Medical men, even if they have not had the advantage of being instructed by so eminent a teacher of virtue as the author of *Moths*, will, in respect of sense of duty to their fellow men, active charity, and self-sacrifice, compare favourably with any body of men whatever. Ouida, of course, has a perfect right to represent a doctor as a murderer, but she has no right to imply that he is a murderer because he is a doctor. When she speaks of the "hells created by modern science," and of the time being near at hand "when there will be no priests and no kings but those of science, and beneath their feet the nations will grovel in terror and writhe in death," she merely talks nonsense; but when she represents the search after scientific truth as naturally leading to crime she utters an infamous falsehood. We have never liked the fashion of Ouida's literary garments, but after reading "Toxin" we are willing to allow that she can write fiction.

DR. RUFFER.

We regret to hear that Dr. Ruffer, the Director of the British Institute of Preventive Medicine, whose researches in regard to the antitoxin treatment of diphtheria are so well known, has himself contracted a severe attack of the disease in the course of his investigations. Immediately on the nature of his complaint being ascertained he was treated by antitoxic serum, and, we are glad to learn, with most satisfactory results, as he is now making very good progress towards recovery.

THE ABUSE OF CLUBS IN GERMANY.

At the meeting of the Deutscher Aerztetag or Diet of German Physicians at Eisenach last week, the chief subjects discussed were the regulation of the relations between medical men and the life insurance companies, and the working of the labourers' medical clubs. The latter question has become of vital importance to the profession. It is calculated that, in accordance with the law enacted a few years ago making it compulsory for every working man, labourer, artisan, clerk, etc., not earning more than a certain amount to be enrolled in a club under supervision of Government, at present more than four-fifths of the whole population have become members of such societies. In consequence,

since that time the amount paid for medical services as a whole has decreased by several millions of marks yearly. The clubs are easily able to obtain doctors willing to accept their appointment at a fixed salary, which, when compared with the work to be done, means a payment of about 2½d. a visit, or less than what a porter considers his due for the same amount of time expended. This would hardly have been possible if the originators of the law, notably Herr von Bötticher, Secretary of State, had not expressed the opinion that as these clubs are organised as a benefit to the people, the doctors are in duty bound to waive all considerations of self-interest, to content themselves with reduced fees, and to do as much work free as Government may think fit to demand. To remedy this ever-growing evil an association was founded in Berlin two or three years ago, calling itself the Verein der freigewählten Casuenaerzte, the "Society of Club Doctors with Unrestricted Selection," meaning that the patients may go to whichever doctor they choose. The statutes are principally these: (The clubs make an agreement with the Association to employ as medical advisers only the members of the Association; the latter accepts as members all qualified reputable practitioners residing in or near the town who are willing to treat the club members at the rates fixed upon; physicians acting contrary to the interests of the club (that is, prescribing in too costly a manner, or encouraging malingersers, for these are the essential points) can be excluded only by decree of the Council of the Association but the clubs have also the right to demand the exclusion in cases of gross infringement of the rules. This method has already proved to be an excellent one. The patients are better satisfied with their attendants, the doctors get a slightly better though still meagre remuneration, and the expenses of the clubs are no higher than before, as the chemists' bills have, by careful supervision, been considerably reduced and malingersers are more promptly detected. Last, but not least, there is now no occasion for necessitous doctors pandering to the vanities and weaknesses of the members of the club Boards, as all appointments are entirely in the hands of the Society's Council. At Eisenach this arrangement was declared by an overwhelming majority (representing about 9,000 votes to 1,000) to be by far the best method; and it is to be hoped that the various medical practitioners throughout the land will soon bring about its accomplishment in other towns besides Berlin.

SUPER-TROPICAL HEAT AT CALCUTTA.

THE heat at Calcutta has been excessive. Out of doors in the middle of the day the shade temperature has been as high as 115°. In many of the offices, notwithstanding all the appliances to cool the atmosphere, a temperature as high as 107° has been recorded, and in the coolest part of the city a temperature of 101° has been the average. Many of the judges have been obliged to adjourn their courts, and commercial business has been practically at a standstill. This intense heat has had a disastrous influence on the health of Calcutta, and the death-rate has risen as high as 58 per 1,000. Rural Bengal has, however, not suffered in the same proportion; for the death-rate has been somewhat below the normal for the same month, and has only reached 25.8 per 1,000. In the towns of Burdwar and Hooghly the death-rate has approached nearly 50 per 1,000. These figures seem to show that in India it is not so much heat which kills, as heat engendering unhealthy conditions in cities, for which scientific sanitation is alone the remedy.

THE total number of students in the Medical Faculty of the University of Sydney during 1904 was 119.

A NATIONAL Medical Congress is being organised by the Portuguese Sociedade de Sciences Medicas. It will probably be held in Lisbon during the festivities in honour of the quatercentenary of the discovery of India by Vasco da Gama.

A REPORT ON THE MILK SUPPLY OF LONDON BY A SPECIAL ANALYTICAL AND BIOLOGICAL COMMISSION.

IN laying before our readers the results of certain investigations which we have recently caused to be made regarding the milk supply to the metropolis, we would commence by some preliminary remarks on the general question of the trade in milk.

So far as legislative action has hitherto interfered to regulate the food supplies of the people, the aim has chiefly been, on the one hand, to prevent adulteration, and, on the other, to prohibit the sale of substances which are injurious to health, whether this arises from decomposition or, in the case of meat or milk, from disease in the animals from which they are derived.

Simple as it would seem to attain these objects, the task has been found in practice to be very difficult. If it is hard to trace the origin of a given piece of meat, how infinitely greater is the chance of error in the endeavour to trace to any particular cow, or even to any particular herd, a sample of milk bought in a London retail milk shop. Nor in estimating the purity of milk is it a matter of merely detecting adulteration; in fact, except so far as concerns the addition of water, which is not in itself a substance foreign to milk, adulteration in its ordinary sense hardly enters into our consideration. It is sophistication that we have to deal with.

SOPHISTICATION OF MILK.

This word is in many ways unsatisfactory, but it has been necessary to find for common use a word which should express the act of tampering with the quality of a substance without any of that addition of something strange or foreign to it which is commonly held to be involved in the term adulteration; and the word which has come into use for this purpose is sophistication. But it must be understood that both these are popular terms, and that in the Acts regulating the sale of food and drugs neither of them is specifically employed, each offence being defined by such words as "mix," "colour," "abstract," etc., while the word "adulteration" has to be applied under existing Acts to all cases where an article is not of the "nature, substance, and quality" demanded or expected by a purchaser.

The two principal methods by which milk as it comes from the cow is manipulated so as to produce the article sold as milk to the consumer are (1) the addition of water; and (2) the abstraction of cream, the skim milk and fresh milk being afterwards mixed in such proportions as to produce a material which will pass the standard accepted or set up by the sanitary authority in the district where it is to be sold.

The first of these is a distinct swindle, a matter of selling as milk what is not and never has been milk, and is also a danger to the public, in that the water used for adulteration may be unfit for drinking purposes, a fact which has been the cause of many an epidemic of enteric fever.

IS IT A FRAUD?

The second is a swindle or not according to the definition adopted of the meaning of the word "milk," and although we are quite clear that milk is a substance produced by the cow, and ceases to be milk when it has gone through any manufacturing processes by which the proportions of its different ingredients are altered, we are quite aware that it is open to argument that milk is a substance that comes from the cow and conforms to certain standards set up by the authorities, and that so long as it conforms to those standards and contains nothing that has not been "milked" from the cow it is

milk. We do not agree with this; we not only consider that the purchasers are thus robbed of the total value of the cream so abstracted, but that, unless much greater precautions are taken than are at all common, the universal mixing involved in the process greatly increases the chances of the milk becoming a means of distributing disease.

Nevertheless, we must not fail to recognise the fact that this method of abstracting cream and then mixing and standardising the residuum is the system under which the modern milk supply of towns is ordinarily provided and is one which is publicly practised, nay paraded, by men and companies of repute.

Milk is also liable to be purposely mixed with antiseptic substances to prevent it turning, besides being more or less accidentally polluted by admixture with a variety of most offensive substances in its transit from the cow to the kitchen; and beyond and anterior to all such chances of deterioration it may, and often is, rendered dangerous as a food in consequence of disease existing in the cow from which it came.

FORMS OF SOPHISTICATION.

It will be admitted then that any efficient inquiry into the milk supply of the metropolis is a matter of almost as great difficulty as it is of interest and importance. Briefly, the sophistications to which milk is liable are:

1. The addition of water—both dishonest and dangerous.
2. The addition of substances intended to prevent decomposition—not, perhaps, of themselves dangerously injurious in the quantities added, but facilitating the sale of stale milk.
3. The addition of substances intended to give colour—generally not injurious.
4. The abstraction of cream or the dilution of a rich milk with milk from which cream has been abstracted—dishonest and in many instances dangerous.
5. Pollution of the milk—always dangerous. This pollution may occur:
 - (a) From the hands of the milkers.
 - (b) By discharges from the genitals and fecal and other matters soiling the udders and teats, and gaining access to the milk.
 - (c) From the use of dirty utensils, either at the dairy or the retail establishment.
 - (d) From the washing of the utensils with dirty or infected water, or from the exposure of the milk or utensils to insanitary emanations, either at the dairy or the retail shop.
 - (e) From the dirty hands or clothes of the milkmen in the streets, and from their careless exposure of the milk during distribution.

In view of this list one is hardly surprised to hear it authoritatively stated that *unsophisticated milk* is practically unknown in the London supply.

THE DIFFICULTY OF THE STANDARD.

In any endeavour to enforce purity it is of the first importance to be able to define what is meant by pure, and it will be seen as we proceed that the establishment of some arbitrary standard of pure milk is an essential preliminary to any effective action being taken to put an end to the wholesale sophistication by which the poor especially are injured and imposed upon.

Roughly speaking milk contains five principal constituents in somewhat the following proportions:

Water	87.17 per cent.
Fat	3.60 "
Proteids	3.35 "
Lactose	4.58 "
Salts	0.71 "

The difficulty, however, which arises in fixing a standard is that there is but little constancy either in these figures or these ratios, for although it may be true that the average milk of a district will almost always give at least 3 per cent. of fat and 8.5 per cent. of solids which are not fat, yet in individual cases cows will certainly give milk of a much poorer character. Thus it happens that those who maintain that whatever can be milked from a healthy cow is milk are able to show extraordinarily poor specimens, which for all their poverty still are milk.

The variations in the composition of milk are indeed very considerable. Stevenson and Murphy give them as follows:

Specific gravity	1028-1034	
Water	85 to 88	per cent.
Cazein, etc.	2.5 " 5	"
Fat	2.7 " 6	"
Lactose	3.5 " 6	"
Salts	0.5 " 0.75	"
Total solids	9.2 " 17.75	"

Thus we see that the total solids may in some cases be nearly twice as great, and the fat more than twice as great as in others.

THE ADULTERATOR'S OPPORTUNITY.

Ample play therefore is given to the adulterator, whose aim is either to produce as large a quantity of passable milk as possible, or else to extract from it as large a quantity of cream as he can, without rendering it unsaleable as pure milk. Usually not only is water added, but cream is removed as well; the raising of the specific gravity produced by the removal of the fat being made up by the addition of water, and on the other hand the lowering of the specific gravity caused by adding water being compensated for by skimming, which tends, by removing the light element, to raise the density. The limit to this process is, however, reached when either the fat or the specific gravity fall below the recognised standard; and when we consider how wide are the limits within which milk is still looked upon as milk, and how frequently, as shown by our analyses, the adulterator oversteps even those bounds, we may judge of the extent to which this comparatively simple and primitive method of adulteration is carried.

WATERED MILK.

The analyses which we are about to publish bring out very clearly the extent to which milk in London is watered. In the meantime we may refer to the report of Mr. Pattinson, the public analyst for Newcastle on Tyne, to which attention is drawn in the Annual Report of the Local Government Board for 1893-94. Speaking of various public institutions of that city, he says that although some of them were supplied with genuine milk, others were receiving milk which had been grossly adulterated. The milk supplied to the workhouse contained 18 per cent. of added water; that to the barracks 36 per cent.; two samples supplied to the Girls' Orphanage, Town Moor, contained respectively 22 and 18 per cent.; two samples supplied to the Deaf and Dumb Asylum 18 and 14 per cent. respectively; and three from the milk supplied to the Fleming Memorial Childrens' Hospital were each adulterated with 30 per cent. of added water.

MODERN MILK SOPHISTICATION.

Experienced milk sophisticators, however, have other methods more difficult to detect than this crude one of mere dilution. The introduction of cream separators has given them the opportunity of removing very cheaply and quickly almost the whole of the fat from milk, dividing the milk, in fact, into a cream much better than what is produced by ordinary skimming, and a skim milk, beside which ordinary "skim" is rich indeed. Moreover, this can be done in so short a time that the "skim" is in no way sour.

The sophisticator has thus the power of either separating his milk in a moderate degree, just taking from it what, from his point of view, is the "excess" of cream; in other words, reducing its cream to the lowest saleable standard without exposing himself to any such risks of detection as would attend the process of "watering," a process by which the total non fatty solids might be so reduced as to lead to detection of the fraud; or he may take off all the cream, using the "skim" to dilute or standardise other fresh milk; or he may sell the "skim," keeping his conscience clear, and leaving it to the retailer to produce, by judicious mixture of his two churns, any quality of milk which the character of his district or the carelessness and indifference of his customers may appear to require; or, finally, he may use the skim milk for making cheese, substituting a sufficiency of some other form of fat for the cream he has abstracted.

If carried out judiciously, and kept within the limits imposed by the standard which the magistrates will accept, it

is next to impossible to prove this form of sophistication, although whenever the inspectors are able to discover the source of the milk, and have an opportunity of milking the cows from which the suspected milk is stated to have been drawn, it is possible to be morally certain that a fraud has been committed.

DIFFICULTY OF DETECTION.

The Report of the Local Government Board for 1892-93 says: "No doubt the chief obstacle in the way of further progress in this matter is to be found in the fact that in the present state of science, analysis fails to distinguish between the water which is a natural constituent of all milk and that which has been added by the dairyman, and therefore an analyst hesitates to condemn a sample of exceedingly poor milk because it may possibly be the genuine product of an old and ill-fed cow, although it has much more probably received an addition of water. He appreciates the fact that the Acts are intended to prevent the sale not of articles of poor quality, but of those which have been fraudulently tampered with; and it would not be in accordance with their design that a poor man should be subjected to penal proceedings because his cow does not produce as good milk as the better-bred and better-fed herd of his richer neighbours. It is the border cases which create the main difficulty." The case for the owners of poor pastures and the breeders of weedy cows could not be better put. On the other hand, writing on the same subject, Mr. Hehner, the public analyst for Derbyshire, observes as follows: "Owing to the natural variation in the composition of milk, the public analyst is bound to pass as genuine all milks which are at least equal in composition to the poorest genuine milk yet found, although in the great majority of cases thus passed he has to do with milk artificially and not naturally weak," showing how this interpretation of the statute tends to degrade the average supply to the level of the lowest known milk.

EXTENT OF THE EVIL.

To appreciate at all the extent to which milk sophistication is carried on in London, we must then remember that the considerations quoted above express the official view, that the authorities at Somerset House decline to accept the higher standard asked for by the Society of Public Analysts, and that while more than one-fourth of all the samples taken in 1893-94 are officially returned as adulterated, that estimate is made on a basis which itself admits of adulteration of all but inferior milk. The want of a series of standards which should express definite nutritive values is well shown by the results of an analysis of 273 individual cows undertaken by Professor Bell at the request of the Local Government Board. The average composition of the milk was as follows:—Total solids, 12.90; solids not fat, 8.91; fat, 3.99. But the total solids in the milk of individual cows was found to range from 10.33 to 15.83 per cent., while the fat in the same manner varied from 2.43 to 5.97.

It is truly stated that "if between these limits a high standard were fixed the result would be to condemn much genuine milk, while if a low standard were adopted pure milk would be watered down to it." The teaching of this, however, is that a series of standards should be fixed, with one or other of which all milk that is sold should conform, and that however "pure" or "genuine" milk may be, it should not be allowed to be sold as whole milk if it is below the lowest standard. The public analyst for Cheshire has taken the trouble to follow up cases of poor milk to their source. In a case in which it did not come up to a very low standard he "found five half-starved cows which were nothing more than animated bundles of bones," and he truly remarks that "it must be perfectly patent to all that the milk supply of the United Kingdom is not to be brought down to such samples."

As things are then, the fact that more than one-fourth of the samples taken in London were found adulterated by no means suggests that only about one-fourth were sophisticated. It only shows that one-fourth were so clumsily or recklessly sophisticated as to overpass even the official limit of low standard milk.

CONDENSED MILK.

It must not, however, be imagined that milk is tampered with only by the milkmen, or the small retail dealers, or

even by the farmers; sophistication also takes place at the hands of companies and those who deal with milk in large quantity, as is shown by the extent to which condensed milk, which is mostly the product of large firms, suffers from the same tendency to degrade the standard to the lowest which is acceptable.

The Local Government Board Report, after giving the number of cases in which condensed milk was found adulterated, draws attention to the further fact that in some cases in which the samples contained little or no butter fat, they were protected by their labels indicating that the article was prepared from skimmed milk. "In some of these cases the words 'condensed milk' were printed in large letters, while upon another part of the label the word 'skimmed,' usually in much smaller type, was introduced." Of this our investigations afford full confirmation.

MAGNITUDE OF THE TRADE.

A word must be added regarding the magnitude of the business of supplying London with milk. In a paper read by Mr. Henry Rew before the Royal Statistical Society, April 26th, 1892, the total quantity of milk brought into London during 1890 by the nine great lines of railway is estimated (chiefly from actual figures furnished by the companies) at 40,431,819 imperial gallons, the amount produced within the metropolitan area at 7,500,000 gallons, and that brought in by road and from other sources 928,000 gallons, making a total of 48,854,000 gallons per year, or a daily consumption of 133,239 gallons of milk in London. In this estimate no account is taken of separated milk or of condensed milk, the use of which is largely increasing, but it is stated in the same paper that the consumption of condensed milk in London in 1890 might be taken at a rough estimate as equivalent to about 6,000,000 gallons of milk. Whether, then, we consider the money value of the milk supplied to London, its dietetic importance, or the loss both in pocket and health suffered by Londoners from its sophistication, we cannot but admit the great importance of making persistent and repeated efforts to maintain its purity at the highest possible standard.

MILKBORNE DISEASE:

AN APPEAL TO MEDICAL OFFICERS OF HEALTH.

MR. ERNEST HART is engaged on a general inquiry into milk-borne disease since 1881, in continuation of his paper of that year on the Influence of Milk in Spreading Zymotic Disease, and will be much obliged if those health officers who possess notes of outbreaks of disease traceable to the agency of milk will be good enough to furnish him with a brief statement of the facts, so far as known, in the shape of answers to the questions subjoined:

1. Date.
2. Locality.
3. Reporter.
4. Total number of cases.
5. Deaths.
6. Number of cases amongst drinkers of suspected milk.
7. Number of persons supplied by milkman.
8. Number of such families involved.
9. Sanitary circumstances of farm or dairy from which milk was obtained.
10. Existing cause of outbreak.
11. Circumstances implicating milk.
12. Facts showing special incidence of disease.
13. Reference to report.

THE GRACE TESTIMONIAL.

THE appeal of the *Daily Telegraph* for subscriptions towards the proposed "Shilling Testimonial" to Dr. W. G. Grace is being so liberally responded to by all sorts and conditions of men, that the *Champion* will receive a very solid and substantial proof of the admiration with which his countrymen regard his prowess in the cricket field. In this truly national testimonial it is peculiarly fitting that the members of the medical profession, to which Dr. Grace belongs, should take part. As doctors we feel an interest in the great cricketer as a splendid example of what exercise and training, under the guidance of a knowledge of the laws of health, can do for the development and preservation of physical vigour; and as Englishmen we are not less proud of him as a representative of all that is best and most wholesome in manly sports. We venture to remind our readers that the subscription list is still open. Letters enclosing contributions to the Fund should have "Grace Testimonial" marked on the envelope.

The following subscriptions have already been received:

Subscriptions already acknowledged	Hastings	Dr. A. Wynter (Buckingham)	Hastings
1	1	C. Rice Morgan (Morrison)	1
A Lover of the Game	1	Mr. D. G. Lewis	1

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held in the Council Room of the Association, at No. 429, Strand (corner of Agar Street), London, on Wednesday, the 10th day of July next, at 2 o'clock in the afternoon.

The following Committees will also meet:

Tuesday, July 9th, 1895.—2.0 P.M. Trust Funds Committee. —2.30 P.M. Premises and Library Committee. —3.0 P.M. Medical Charities Committee. —3.30 P.M. Branch Organisation Committee. —4.30 P.M. Parliamentary Bills Committee. *Wednesday, July 10th, 1895.*—11.0 A.M. Journal and Finance Committee.

FRANCIS FOWKE, General Secretary.

July, 1895.

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

MEMBERS are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the offices of the Association, 429, Strand. The rooms are open from 10 A.M. to 5 P.M. Members can have their letters addressed to them at the Office.

NOTICE OF QUARTERLY MEETINGS FOR 1895.

ELECTION OF MEMBERS.

MEETINGS of the Council will be held on July 10th and October 23rd, 1895. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before the meeting—namely, October 2nd, 1895.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWKE, General Secretary.

BRANCH MEETINGS TO BE HELD.

NORTH WALES BRANCH.—The forty-sixth annual meeting will be held at the George Hotel, Cardigan, on Thursday, July 12th, at 1 P.M. After the usual formal business, the President-elect, Mr. T. Hunter Hughes, Coroner for South Carmarthen, will deliver his address. Richard Jones, M.D., D.P.H. Cantab., Festing Quarry Hospital, will read a paper on Disease and Death among Quarrymen—a statistical inquiry. R. H. Mills Roberts, F.R.C.S. Edin., Llanberis Quarry Hospital, will read notes on a case of Ovarian Dislocation of the Femur. Henry Evans, M.R.C.S. Eng., Portmadoc, will show cases of: (1) Progressive Muscular Atrophy; (2) Progressive Muscular Atrophy Complicated with Epilepsy; (3) Myotonia in a Young Person.—W. Jones Morris, Honorary Secretary, Portmadoc.

LANCASHIRE AND CHESHIRE BRANCH.

The fifty-ninth annual meeting of this Branch was held in University College, Liverpool, on June 19th, Dr. EDWIN RAYNER, President, in the chair. About 200 members were present.

Confirmation of Minutes.—The minutes of the previous annual and three intermediate meetings were read and confirmed.

Installation of New President.—Dr. RAYNER then introduced his successor in the Presidential chair, Mr. W. MITCHELL BANKS, who delivered an address on Overcrowding in the Medical Profession and its Remedy.—On the motion of Dr. RAYNER, seconded by Mr. JAMES TAYLOR, a hearty vote of thanks was accorded to the President for his very able address.

Report of Council.—The report of Council stated that the year had been marked by great activity, and such important subjects as the amendment of the Medical Acts, and certain alterations in the laws of the Branch had been under serious consideration. There had been no fewer than ten Council meetings, and three special meetings of the members of the Branch. The Branch showed a steady growth, though the accession of new members had not been so great as in the preceding year. There had been 67 new members elected, while the number of old members had been depleted by 14 deaths and 17 resignations, the majority on account of removal from the district. Among the deaths was specially mentioned that of Mr. Christopher Johnson, of Lancaster, a former President of the Branch, and one who took an active interest in all matters appertaining to the Association. There were now on the roll 988 members, which was the highest record to which the Branch had attained. The credit balance at the end of last year was £416 7s. 5d., being £130 7s. 8d. less than that of the preceding year. This had arisen from the exceptionally heavy expenditure of £280 3s. 6d., of which the Branch Committee had been directly responsible for £181 2s. 5d. The important resolution passed at the special meeting in Liverpool, on the motion of Mr. Walter Whitehead.

That in any Bill aiming at the suppression of unqualified practice, the act of having practised medicine, surgery, or midwifery, for gain or profit, by a person unregistered under the provisions of the Medical Acts, should be made penal,

had been referred along with other questions of an allied nature by the Parliamentary Bills Committee to a Subcommittee of that body. As one of the representatives of the Branch, Dr. Woodcock, had been placed on that Subcommittee, there could be no doubt but that the views of the Branch would be ably expounded. The alterations in the laws had given rise to considerable discussion, and perhaps to much divergence of opinion; but it was to be hoped that in their present form they would answer the requirements of the Branch for some time. The harmonious result of this election augured well for their efficiency. It was hoped that everyone would strive to increase the numbers and augment the influence of this great Branch. A cordial invitation, which had been provisionally accepted by the Council, had been received from the members resident in Southport, to hold its next annual meeting in that town.

Financial Statement.—The financial statement showed a balance to the credit of the Branch of £416 7s. 5d. On the motion of Dr. WATKINS, seconded by Dr. HAYWARD, the report of Council and the financial statement were received and adopted.

Election of Officers and Council for 1895-96.—The SECRETARY announced that the following members had been elected to their respective positions in the Council, in accordance with the laws of the Branch:—*President:* W. Mitchell Banks, F.R.C.S., Liverpool. *President-Elect:* H. H. Vernon, M.D., Southport. *Vice-Presidents:* J. Nelson Cregeen, Liverpool; Walter Whitehead, F.R.C.S. Edin., Manchester. *Honorary Secretary:* James Barr, M.D., Liverpool. *Representatives on the Council of the Association:* J. Barr, M.D., Liverpool (General Secretary); E. H. Dickinson, M.D., Liverpool; George B. Barron, M.D., Southport; James Taylor, Chester; Samuel Woodcock, M.D., Manchester. *Representatives on Parliamentary Bills Committee:* G. E. Shuttleworth, M.D.; James Taylor, F.R.C.S.; C. T. Street; Samuel Woodcock, M.D.

Members of Council: William Armstrong, Manchester; W. Bain, M.D., Heaton Chapel; *W. H. Barr, Bury; E. H. Beaman, Southport; W. Berry, Wigan; H. W. Boddy, M.D., Manchester; T. R. Bradshaw, M.D., Liverpool; *J. B. Brierley, M.D., Manchester; W. M. Campbell, M.D., Liverpool; *C. G. Campbell, Uppermill; William Carter, M.D., Liverpool; J. M. Chisholm, M.D., Woolton; R. Crean, M.D., Manchester; A. Davidson, M.D., Liverpool; *T. Fort, Oldham; *J. G. Gledhill, Manchester; A. Godson, M.B., Cheshire; A. Hamilton, Chester; Nathan Hannah, Ashton-in-Makerfield; A. O. R. Harris, M.D., Birkenhead; R. Harris, M.B., Southport; T. E. Hayward, M.D., Haydock; *John Hadden, Preston; E. W. Hope, M.D., Liverpool; *W. H. Hughes, Ashton under Lyne; F. M. Johnson, M.D., Salford; J. Lambert, M.D., Birkenhead; H. Colley March, M.D., Rochdale; J. M. H. Martin, M.D., Blackburn; B. J. Massiah, M.D., Didbury; *J. E. Moreton, Tarvin; R. A. Murray, M.D., Stockport; *J. T. Neech, Tyldesley; H. Laird Pearson, Birkenhead; Chauncy Puzey, Liverpool; *E. Rayner, Stockport; C. J. Renshaw, M.D., Ashton-on-Mersey; *A. Brown Ritchie, M.B., Manchester; D. Lloyd Roberts, M.D., Manchester; *R. Robertson, M.D., Liverpool; *A. Samuels, M.D., Liverpool; T. Starkey Smith, M.D., Warrington; *J. Thornley, M.D., Bolton; Charles Thorp, Todmorden; Francis Vacher, Birkenhead; G. E. Walker, Liverpool; William Walter, M.D., Manchester; J. W. Watkins, M.D., Newton-le-Willows; *John Watson, Manchester; W. W. Wingate-Saul, M.D., Lancaster. *New nominations—being gentlemen who were not ordinary members of Council, within the last twelve months.

Place of Next Annual Meeting.—On the motion of Dr. BARRON, seconded by Dr. ROBERT HARRIS, it was unanimously resolved that the next annual meeting be held in Southport.

Auditors.—On the motion of Dr. HUGHES, seconded by Dr. BARRON, Dr. D. O'Sullivan and Dr. Joseph Thornley were appointed auditors for the next twelve months.

Vote of Thanks.—On the motion of Mr. COLIN CAMPBELL, seconded by Dr. G. G. STOPFORD TAYLOR, a hearty vote of thanks was accorded to the retiring President, Vice-Presidents, General Secretary, and other members of Council for their services during the past year.

The Case of Mr. W. H. Manifold.—The SECRETARY drew the attention of members of the Branch to the fund which is being raised in Liverpool for Mr. W. H. Manifold, formerly an active member and Vice-President of the Branch, who, in consequence of failing health and failing practice, was now entirely destitute of means. Subscriptions will be thankfully received by the Branch Secretary, Dr. James Barr, or by the treasurer of the fund, Mr. G. E. Walker, 45, Rodney Street, Liverpool.

Payment of Railway Fares of Representatives on the Parliamentary Bills Committee.—On the motion of Dr. BARRON, seconded by Dr. CARTER, it was resolved:

That the first-class return railway fares of the representatives of the Lancashire and Cheshire Branch on the Parliamentary Bills Committee be paid out of the funds of the Branch, excepting the fares of representatives who shall also be members of the Council of the Association, but in the event of any meeting of such Committee or of a Subcommittee being convened other than at the usual quarterly meetings then the fares of such members be paid.

The British Medical Association and the Protection of the Interests of the Medical Profession.—The SECRETARY brought forward some communications which he had received from Dr. Broadbent, of Manchester, and Dr. Welsford, of Dover, respecting a resolution which would be proposed at the annual meeting of the Association in London. The Secretary explained that the proposal seemed to him tantamount to an amalgamation of the Medical Defence Union with the British Medical Association. After some discussion the following resolution was proposed from the chair and carried unanimously:

That it is to the interest of the public and of the medical profession that the Council of the British Medical Association should take power and authority to protect both the individual and collective interests of the medical profession, and that the Council be requested to take such steps as may be necessary to enable it to actively undertake these duties.

Communications.—The following communications were pre-

presented.—Dr. Wm. ARMSTRONG: The "Naheim" Bath and Exercises in Cardiac and Allied Diseases.—Mr. COLIN CAMPBELL: On the Range of Utility of Intrapulmonary Medication (demonstration).—Dr. G. C. STOPFORD TAYLOR showed Oases, Water-colour Drawings, and Photographs of Rare Skin Diseases.—Dr. FRANK BARRETT showed Cases of Rare Skin Diseases.—Professor BOYCE gave a Pathological Demonstration with Illuminated Illustrations.—Mr. ROBERT PARKER: Torn Semilunar Cartilage of Knee, cured by Operation (Two Patients).—Mr. JAMES HARRISON: Five Patients illustrating Brain and Nerve Surgery.—Mr. E. STANMORE BISHOP: On Ventro- and Vagino-fixation of the Uterus.—Mr. W. ROGER WILLIAMS: On the Increase of Cancer.—Mr. W. MITCHELL BAKER showed Patients on whom various Intestinal Operations had been performed.—Mr. F. T. PAUL: Case of Felson Grafting.—Mr. G. GIBSON HARRISON: Two Specimens of Colectomy in which Murphy's Buttons were used.—Dr. JAMES BARR: The Treatment of Meningitis.

Laboratories.—The Engineering, Chemical, and Pathological Laboratories of University College were open for the inspection of members.

Exhibition.—An Exhibition of Drugs and Surgical Appliances was held in the Museum.

Luncheon.—A luncheon, provided by the President and members of the Branch in Liverpool was served at University College from 1 to 3 P.M.

Dinner.—The annual dinner was held at the Adelphi Hotel. There were 70 members present, and the President (Mr. Mitchell Banks) occupied the chair. After the usual loyal toasts, the President gave "The Ministers of Religion" and "The Legal Profession," to which the Rev. T. W. LUND and the City Coroner (Mr. Samson) respectively replied. The Secretary replied for "The Lancashire and Cheshire Branch," which was happily proposed by the Rev. T. W. LUND. Many good things were said about University College both by Mr. STEWART and Principal RENDALL, while a hearty vote of thanks was accorded to Professor Hele Shaw for kindly placing his department at the disposal of the Branch. The toast of "The Health of the President" terminated a very enjoyable day's proceedings.

EDINBURGH (LOTHIANS AND FIFE) BRANCH.

The twentieth annual meeting of this Branch was held in the Hall of the Royal College of Physicians of Edinburgh, on June 27th, Dr. ARGYLL ROBERTSON, Vice-President, in the chair.

Confirmation of Minutes.—The minutes of Branch meeting of January 11th, 1895, were read and approved.

New Members.—Intimation was made that the following gentlemen had been admitted members of the Association by the Council of the Branch: Robert Hutchison, M.B., C.M., George Campbell Laing, M.B., C.M., and Andrew Fleming Wood, M.B., C.M. The following applicants having been balloted for were admitted to the membership of the Branch: John Anderson, M.B., E. F. Armour, M.B., J. W. Ballantyne, M.D., R. J. A. Berry, M.D., T. Brown Darling, M.D., J. Halg Ferguson, M.D., Andrew Gilmour, L.R.C.P.E., Robert Hutchison, M.B., Claude B. Kerr, M.R., George C. Laing, M.B., J. H. A. Laing, M.B., John Nowell, M.D., William F. Robertson, M.B., Ernest George Scott, L.R.C.P., and S. E. A. R. Simpson, M.D., A. Logan Turner, M.D., A. Stodart Walker, M.B., J. O. Webster, M.D., and Andrew Fleming Wood, M.B.

Treasurer's Statement.—The Treasurer presented his annual statement, which showed a balance in favour of the Branch of £40 10s. 6d. The statement showed an excess of expenditure over income to the amount of £9 4s.

Election of Officers.—Dr. Nasmith (Cupar, Stockman, and Norman Walker were elected members of the Branch Council in room of Drs. Aitken, Dow (Dunfermline), and James Ritchie, who retire by rotation. Dr. William Russell was re-elected Representative of the Branch on the Council of the Association, and Dr. James Ritchie on the Parliamentary Bills Committee. The other officers elected were re-elected. On the motion of the Secretary, seconded by Dr. BALFOUR (Perth), it was agreed that the Representative of the Branch on the Parliamentary Bills Committee be in-

vited to be present at the meetings of the Branch Council during the ensuing year, so as to advise the Council as to the proceedings of the Central Committee.

Midwives' Registration.—The following amended report of the Committee on the question of midwives' registration was adopted on the motion of Dr. HART, seconded by Dr. P. A. YOUNG. It was thereafter moved by Dr. A. BALFOUR, and seconded by Dr. CORSMACK SMITH, that the report be transmitted to the Council of the Association. An amendment was moved by Dr. R. W. PHILIP, seconded by Dr. INGLAND, that the report be remitted, along with additional papers on the subject, for the further consideration of the Committee. The motion was carried by a majority.

Your Committee beg to report their disapproval of the principle of the registration of midwives, but strongly support improvement in the instruction of midwifery nurses. Your Committee understand by midwife a person who undertakes on her own responsibility the care of a woman by a midwifery nurse a woman who undertakes the care of a woman under the supervision of a medical practitioner. Your Committee are of opinion that a woman, unless a legally qualified medical practitioner, is not competent to attend on her own responsibility even so-called normal labour, as sudden complications may arise in her apparently normal labour, which require prompt and active treatment, which such women are not qualified to undertake, is demanded. The diagnosis of complications must be in a number of instances beyond the midwives' power, and this will inevitably lead to delay in sending for skilled assistance. Legal registration of imperfectly trained women would lay on the medical profession, who would be the teachers and examiners, the onus of any dangers and evils which might arise. Your Committee are further of opinion that legal registration would open the door to serious abuses in the treatment of infants, and of the diseases peculiar to women. But while expressing any proposals in the direction of founding a new order of registered midwives, your Committee are of opinion that the training of midwifery nurses, to act under a qualified practitioner, should be as thorough and practical as possible, and should be restricted to those public institutions which can satisfy the General Medical Council that they have sufficient facilities for the purpose.

Dr. Philip recorded his dissent on the ground that the report was too immature for publication. The Committee was thereafter continued.

Abuse of Medical Charities.—On a communication from the Council of the Association regarding the abuse of medical charities, it was agreed that the questions raised were not suitable for application within the district represented by the Branch.

The Cork Branch and the Benefit Societies.—A communication from the Council of the Association relative to the Cork protest against benefit societies was allowed to lie on the table.

The British Medical Association and Medical Defence.—The following motion, submitted by Dr. JAMES RITCHIE, and seconded by Dr. SPENCER (Burntisland), was adopted unanimously:

That it is to the interest of the public and of the medical profession that the Council of the British Medical Association should take powers and authority to protect, not only the collective interests of the medical profession, but also those of the individual members of the Association, and that the Council be requested to take such steps as may be necessary to enable it actively to undertake those duties. This Branch recognises that probably these steps include an alteration in the Articles of Association and the raising of the annual subscription.

It was agreed that a copy of the motion be sent to the Secretaries of all the Branches of the Association in the United Kingdom.

Royal Medical Benevolent College.—On a statement by the Secretary, the Branch reaffirmed its interest in the Royal Medical Benevolent College, and recommended its claims to the consideration of the members.

The Dr. Allan Testimonial Fund.—It was announced that a sum of £80 9s. had been subscribed through the Committee of the Branch towards the Dr. Allan Indemnity Fund. The Committee were instructed to make arrangements for the presentation of the testimonial as they might see fit in the circumstances.

Boundary of Branches.—With regard to the boundary of Branches, a letter was read from the General Secretary to the effect that there is no by-law to prevent a member joining a Branch other than that of the district in which he resides, and that, so far as the by-laws go, a member of the Association can, if elected, belong to any number of Branches he desires.

Joint County Meeting.—Intimation was made that the Council had arranged for the holding of a joint meeting with the Stirling, Kinross and Clackmannan and other Branches at Stirling on Tuesday, July 2nd.

Votes of Thanks.—The meeting terminated with a vote of thanks to the Chairman and to the Royal College of Physicians for the use of the hall.

SOUTH MIDLAND BRANCH.

THE fortieth annual meeting of this Branch was held at the General Infirmary, Northampton, on June 27th. Forty members and visitors were present, and were, previously to the meeting, entertained at luncheon by the President, Dr. A. H. Jones.

New Members.—Mr. Alfred Stanbury Phillips and Mr. Frederick Paul Mandel, of Bedford, were elected members of the Association and Branch. Mr. Robert L. Brander, of Aspley Guise; Mr. Edward Somerset, Oundle; and Dr. P. Murray Braidwood, Amersham, were also enrolled as members of the Branch.

Autumnal Meeting.—It was resolved that the autumnal meeting of the Branch be held at Olney on October 3rd.

Election of Officers.—President for 1896-7: Mr. Geo. H. De'Ath, Buckingham. *Committee of Management:* Dr. Bazzard, Mr. Milligan, Mr. Crew, Dr. Walker, for Northamptonshire; Dr. G. P. Goldsmith, Mr. Kinsey, for Bedfordshire; Mr. Rogers, Mr. De'Ath, for Buckinghamshire. *Representative on General Council and on Parliamentary Bills Committee:* Mr. J. Hughes Hemming. *Honorary Treasurer:* Mr. G. H. Percival. *Honorary Secretary:* Mr. O. Jewel Evans.

Alteration of Rule.—An alteration was made in Rule 3, paragraph 2, as to the number of members in and the method of electing the Committee of Management. An additional member was appointed for Bedfordshire, and it was decided that each county, or division of the Branch, should elect its own representatives only; such election to take place at the annual meeting, and by the ballot of those members only who were present.

Abuse of Medical Charities.—A letter was read from the General Secretary on the subject of the abuse of medical charities, expressing a hope that the Branch would make inquiries in its own district, and, if desirable, suggest remedies. Letters were also read from the staffs of several hospitals in the district, stating that no obstacles would be placed in the way of an investigation. A long discussion ensued, and ultimately a small subcommittee was appointed to investigate the matter and report.—The CHAIRMAN read a circular received from some members of the South-Eastern Branch, embodying a resolution asking the Council of the Association to undertake the duties of medical organisation, medical defence, etc. Mr. R. H. KINSEY also read a paper dealing with the grievances in the profession, which led to a good discussion, and he proposed the following resolution, which was put to the meeting and carried unanimously:

That the Council of the British Medical Association be urged to lose no time in investigating thoroughly and impartially the relations of medical men to dispensaries, medical aid societies, and the Poor-law authorities, with a view to advising how they shall be regulated to the greatest advantage of the country, the poor, and the profession.

Cork Branch.—A letter was read from the General Secretary on the subject of the action taken by the Cork doctors, with resolutions of the General Council on the same. A donation of £5 from the Branch funds was voted to the Cork Branch of the Association, together with an expression of sympathy with them in their recent action.

President's Address.—Dr. A. H. JONES delivered a presidential address, taking for his subject a historical account of former medical and surgical worthies connected with the town and the infirmary, many of whose portraits were displayed in the room. On the proposition of Dr. GOLDSMITH, seconded by Mr. VESSEY, a cordial vote of thanks was accorded to Dr. Jones for his able and interesting historical address.

Papers and Cases.—Mr. W. G. NASH (Bedford) read a paper on Adenoids, their Diagnosis and Treatment. He showed numerous specimens, with the instruments he employed in their removal. Mr. WINCKWORTH agreed with the reader in the advantages of chloroform over ether in operating on these cases. Mr. MILLIGAN considered the finger was by far the best instrument. Mr. HEMMING, the CHAIRMAN, and others made remarks, and Mr. NASH replied.—Dr. W. HARDING (Bury Wood, Northampton) read a paper on Some Practical

Points in the Management of the Acutely Insane in Private Houses. Dr. BOWEN agreed with the speaker as to the desirability in many such cases of asylum medical officers consulting with private practitioners, a thing, however, impossible in the present state of the law. Mr. HEMMING, Mr. JACOBS, Mr. WINCKWORTH, and the CHAIRMAN also made remarks, and Dr. HARDING replied. The paper was listened to with much interest.—Mr. R. A. MILLIGAN related Two Cases of Recurrent Appendicitis successfully treated by Resection of the Vermiform Appendix. He showed the appendices removed, and Mr. NASH and others made remarks.

Votes of Thanks.—Hearty votes of thanks were accorded to the retiring President (Dr. Coombs) for his efficient services during his year of office; to the readers of papers; and to the President for his conduct in the chair, on the proposition of Mr. LINNELL, seconded by Dr. UNDERWOOD (Hastings), who was present as a visitor.

BATH AND BRISTOL BRANCH.

THE annual meeting of this Branch was held at Bath on June 26th. The chair was taken by Mr. NELSON C. DOBSON, the retiring President, and thirty-eight members and one visitor were present.

New Member.—Mr. G. M. Keavil, M.R.C.S., L.R.C.P., L.D.S., of Bath, was elected a member.

Installation of the New President.—Mr. DOBSON resigned the chair to Dr. CAREY COOMBS, who delivered the presidential address. A vote of thanks to the President for his interesting and valuable address was moved by Dr. GOODRIDGE, seconded by Mr. POOLE LANSDOWN, and carried by acclamation.

Report of Council.—Mr. W. M. BRAUMONT, Honorary Secretary for the Bath District, read the report of the Council, which stated that the total number of members was now 286; 17 new members had been elected during the year, 1 in the Bath Section and 16 in the Bristol. There had been 4 resignations in the former district and 8 in the latter, owing principally to the removal of members from the neighbourhood. Five members had been lost by death: Mr. G. E. Alford, of Weston-super-Mare; Mr. Corbould, Mr. Lovell, Mr. Metford, and Mr. Pritchett. Mr. Alford's loss was keenly felt by an unusually large number of friends and patients. His kindness of heart, his willingness to enter into and help to alleviate the troubles of the numerous sufferers that he was daily brought into contact with, his strict probity of life, and his genial bearing endeared him to those who knew him, and his professional friends could bear testimony not only to his high medical and surgical skill, but also to his consistent upholding of the principles that make intercourse between the members of the profession a pleasure. Mr. Corbould, who was one of the consulting surgeons of the Bristol Dispensary, had been a member of the Branch for many years, and though for a long period an infrequent visitor at its meetings, he continued to take a keen interest in its proceedings; he could, however, plead with more justice than most men, as an excuse for this absence, the absorbing cares of one of the largest general practices in the provinces, which he conducted with conspicuous success until almost the last hour of his life. Mr. J. S. Metford was Honorary Surgeon to the Clifton Dispensary. At an early period he took diseases of the ear as a speciality, and for more than forty years was surgeon to a dispensary for diseases of the ear in Clifton. He manifested a practical interest in the Medical Benevolent College, and was the local honorary secretary and treasurer for that important place of education. He was much beloved by his circle of patients. Twenty-one communications had been made at the ordinary meetings during the session, and numerous patients had also been exhibited. The meeting at Bath on February 27th was devoted to a valuable discussion on the Surgery of the Thyroid Gland, which was ably introduced by Mr. R. J. H. Scott. The following gentlemen had been elected to fill the vacancies on the Council: Bath Section: Mr. Goss, Mr. Ransford, Mr. Gaine. Bristol Section: Dr. Aust-Lawrence, Dr. Harrison, Mr. Harcourt. The financial condition of the Branch was satisfactory, the balance-sheet showing a balance in hand of £30 17s. 0d. The Council recommended a donation of £10 10s. to the Medical Benevo-

lent Fund, and a contribution of £5 5s. to the Royal Medical Benevolent College. In response to a letter from the Council of the Association suggesting an inquiry as to whether there was any abuse of medical charities in this district, the Local Council have appointed the following Subcommittee to consider the question and report upon it: For Bath: Dr. Preston King, Dr. Bannatyne, Dr. Ellis, Mr. Hopkins, Dr. Williams, Mr. Bloxam, Mr. Flemming, Dr. Wigmore, Mr. Martin, Mr. Harper, For Bristol: Drs. Jas. Swain, P. W. Williams, Parker, Lansdown, Rogers, and Powell, and Messrs. Dacre, Gibbs, Walker, Carter, Logan, Fendick, Hedley Hill, and Mr. Dobson (President), and Dr. Markham Skerritt (Secretary). The Branch had lost the advantage of the services of Dr. E. Markham Skerritt, as Secretary, a position which he had energetically filled for fifteen years. He was nominated President-Elect, and Dr. J. Michell Clarke was nominated Secretary in his place.

It was proposed by Mr. Goss, seconded by Dr. LANSDOWN, and resolved unanimously:

That the report and financial statement now read be received and adopted.

Election of Officers.—The following were elected:—*President-Elect*: Dr. E. Markham Skerritt. *Secretary for the Bristol District*: Dr. Michell Clarke. *Representatives of the Branch on the Council of the Association*: Mr. R. S. Fowler and Dr. E. Markham Skerritt. *Representative of the Branch on the Parliamentary Bills Committee*: Dr. Harrison.

Votes of Thanks.—A vote of thanks to the retiring President for his courteous and able conduct in the chair during the past year was proposed by Dr. SHINGLETON SMITH, seconded by Mr. C. E. S. FLEMING, and carried by acclamation; and a vote of thanks to the Council and the Secretaries for the past year, with a request to Mr. W. M. Beaumont to continue in office, was proposed by Mr. CROSSMAN, seconded by Dr. F. STOCKWELL, and carried unanimously. Dr. ELLIS proposed, Dr. RATTRAY seconded, and it was carried unanimously that a vote of thanks be passed to the President and Governors of the Royal Mineral Water Hospital for the use of their Board room.

Annual Dinner.—The members afterwards dined together at the Grand Pump Room Hotel.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.

MIDWIVES' REGISTRATION.

In consequence of a further letter from Dr. Fiddian, of Cardiff, we have communicated with Dr. A. Sheen, the Secretary of the South Wales and Monmouthshire Branch, who informs us that the somewhat complicated history of the action of the Branch in the matter of midwives' registration is as follows:

At a meeting at Neath, on April 26th, 1894, the following resolution was proposed and seconded:

That this meeting recognises the necessity, in the interests of the public, for legislation to secure the proper education, registration, and supervision of midwives, and upholds the principle advocated by the Midwives' Registration Association that the education and registration of midwives should be under medical control and supervision.

The following amendment was then proposed and seconded:

That this meeting declines to express an opinion as to the advisability or otherwise of the registration of midwives until the Bill is before the profession.

When put to the vote the amendment was lost by a majority of two to one. The resolution, put from the chair, was carried *non. com.*

At a meeting at Pontypool on October 25th, 1894, Dr. Sheen read a communication from the Midwives Registration Association enclosing a copy of their scheme, and it was resolved that copies of the scheme should be obtained, and circulated to each member with a view to its discussion at a special meeting.

This special meeting was held on December 13th, 1894. There was no formal discussion, but it was resolved:

That the subject of midwives' registration be discussed at the next meeting of the Branch.

At the next meeting of the Branch held at Aberdare on February 28th, 1895, it was resolved:

That the scheme for the registration of midwives submitted by the Midwives' Registration Association should lie on the table.

BRITISH GUIANA BRANCH.

The second quarterly meeting of this Branch was held in Georgetown on May 30th; Dr. WALLBRIDGE, President, in the chair. Fifteen members were present.

Medical Annual.—The President announced that the publication of the *Medical Annual* would be proceeded with, though the full amount required had not yet been promised.

Certificated Midwives.—The President also announced that the Medical Board had altered the official title of certificated midwives to "nurse midwives."

Tropical Fevers.—A discussion then took place on Tropical Fevers, opened by the President, in which most of the members took part. The discussion was adjourned till the next meeting, when the adjourned discussion will be opened by Dr. Ross, Surgeon-General of the colony.

Specimens.—The following specimens were shown by Dr. DANIELS (Secretary): (1) A new Tapeworm found in an aboriginal; it measured 8 inches in length, and in the mature segments the embryos were arranged in ball masses, in this it closely resembled *Tænia Madagascariensis*, but differed in length, in the number of segments, over 300, in the size of egg masses, and of the number of embryos in each mass, as well as in size and number of segment in which genital organs first appeared and first became mature; (2) a Persistent Hyaloid Artery; (3) a Calculus removed by lateral lithotomy in an adult (the second recorded lithotomy in the colony); and (4), for Dr. CARTER, a Fistulous Communication between a Perinephritic Abscess and the Large Intestine.

BRITISH MEDICAL ASSOCIATION.

SIXTY-THIRD ANNUAL MEETING.

The sixty-third Annual Meeting of the British Medical Association will be held in London on Tuesday, Wednesday, Thursday, and Friday, July 30th, 31st, August 1st and 2nd, 1895.

President: E. LONG FOX, M.D. Oxon., F.R.C.P., Consulting Physician to the Bristol Royal Infirmary.

President-Elect: Sir J. RUSSELL REYNOLDS, Bart., M.D. F.R.C.P., F.R.S., President of the Royal College of Physicians.

President of the Council: J. WARD COWINS, M.D. Lond., F.R.C.S., Senior Surgeon to the Royal Portsmouth Hospital.

Treasurer: HENRY TRENTHAM BUTLIN, F.R.C.S., D.O.L., Surgeon to St. Bartholomew's Hospital, E.C.

An Address in Medicine will be delivered by Sir WILLIAM BROADBENT, Bart., M.D., F.R.C.P., Physician-in-Ordinary to H.R.H. the Prince of Wales.

An Address in Surgery will be delivered by JONATHAN HUTCHINSON, F.R.S., F.R.C.S., Consulting Surgeon to the London Hospital.

An Address in Physiology will be delivered by EDWARD ALBERT SCHÄFER, F.R.S., Jodrell Professor of Physiology, University College.

The Scientific Business of the Meeting will be conducted in Fifteen Sections, as follows, namely:

A. MEDICINE.

Lecture Theatre—Conjoint Examination Hall.

President: F. W. PAY, M.D., F.R.S. **Vice-Presidents**: Sir FREDERIC BATMAN, M.D.; D. W. FINLAY, M.D.; W. S. CHURCH, M.D.; J. W. MOORE, M.D.; STEPHEN MACKENZIE, M.D.; E. MARKHAM SKERRITT, M.D. **Honorary Secretaries**: WILLIAM COLLIER, M.D., St. Mary's Entry, High Street, Oxford; W. P. HERRINGHAM, M.D., 13, Upper Wimpole Street, W.; Sir HUGH R. BRAY, M.D., 18, Serjeant's Inn, Fleet Street, E.C.

The following subjects have been selected for discussion:—

Wednesday, July 31st.—I. Discussion on Diphtheria and its Treatment by the Antitoxin embracing the following points: (1) Pathology of Diphtheria and its Sequelæ; (2) Symptoms and Progress; (3) Statistics of Mortality under the Antitoxin Treatment and under other Treatment; (4) Effect of the Antitoxin Treatment upon the Local Affection, upon the General Condition, and upon the Sequelæ; (5) Effects that may arise from the Antitoxin Treatment. Introduced by Sidney H. O. Martin, M.D. The following

to intend to join in the discussion: G. Sims Woodhead, D.; E. W. Goodall, M.D.; Claude Muirhead, M.D. (if possible); Alex. Johnston, M.D.

Thursday, August 1st.—II. Discussion on Acute Lobar or suppurative Pneumonia, its Etiology, Pathology, and Treatment. Introduced by Douglas Powell, M.D. The following have announced their intention of taking part in this discussion: Professor Clifford Allbutt; Samuel Barton, M.D.; Mayoy Coupland, M.D.; Samuel Gee, M.D.; G. A. Gibson, D.; James E. Pollock, M.D.; Walter G. Smith, M.D.; Sir Grainger Stewart; T. Henry Green, M.D.; W. R. Thomas, D.; G. W. Balfour, M.D.; David Finlay, M.D.; Arthur Newell, M.D.; J. Dreschfeld, M.D.; Alfred Barrs, M.D.; A. Auld, M.D.; J. Sinclair Coghill, M.D.; F. M. Pope, M.D.; Lovell Drage, M.D.; Samuel West, M.D.

Friday, August 2nd.—III. Discussion on the Causes of Auto Rheumatism and its Relation to other Affections. Introduced by W. B. Cheadle, M.D. The following will join in the discussion: Archibald Garrod, M.D.; J. F. Goodhart, M.D.; Alfred Mantle, M.D.; J. T. MacLagan, M.D.; Newsholme, M.D.; P. G. Latham, M.D.; H. Handford, M.D.; Sir Iyze Duckworth, M.D.; A. Baig, M.D.; T. Munton, M.D.; H. Lane, M.D.; M. K. Hargreaves, M.D.; H. Calley, M.D.; M. Charteris, M.D.; Samuel West, M.D. The following also hope to take part in these discussions: Magee Finny, M.D.; C. F. Nixon, M.D.; Alfred Parsons, D.; M. A. Boyd, M.D.; J. O. Carroll, M.D.; Richard A. Gays, M.D.; H. O. Tweedy, M.D.; J. A. Lindsay, M.D.; C. Pearson, M.D.; R. J. Kinkead, M.D.; Walter Bernard, D.

The following papers have been announced:

ANDERSON, F. H., M.D. Latent Ulcer of the Stomach.
 CAMPBELL, Collie, M.R.C.P. On Intratracheal Treatment.
 CAMPBELL, Arnold, M.D. Phthisis in Relation to Heart Disease.
 COCHRAN, J. Sinclair, M.D. The Hypodermic Use of Gualacol in Acute Bronchial Tuberculosis.
 DAVIES, Arthur T., M.D. An Account of Fourteen Cases of Myxodema.
 DRESCHFELD, Julius, M.D. On Ataxic Paraplegia.
 FAWCETT, Arthur, M.D. Hypertrophic Cirrhosis of the Liver.
 GILLES, H. Cameron, M.D. The Natural History of Pain.
 GILES, E. Lloyd, M.D. Chlorosis.
 GUN, Hugh, L.R.C.P. Chronic Rheumatic Arthritis: further points in its differentiation from Chronic Rheumatoid Arthritis.
 HARRIS, Arthur E., M.D. The Use of Alcoholic Stimulants and their Relation to True Physiological Health.
 HARRISON, Alexander, M.D. The Treatment of Aortic Valvular Disease.
 HENRY, G., M.B. The Exceptions to Colles's Law and their Practical Teaching.
 JONES, Alfred, M.D. Arsenical Multiple Neuritis following the Application of a Cancer Cure.
 KINGSLEY, E. R., M.D. A Point in the Diagnosis between Chronic Bronchitis and Chronic Gout.
 LOCKWOOD, William, M.R.C.S. Notes on the Influence of Heredity in Disease.
 LUNDA, Professor. Sur la Toxicité des urines dans son degré et dans son non-graphisme comme élément de diagnostic et de pronostic dans les maladies en général, et surtout dans les maladies aiguës infectieuses.
 MITCHELL, W. Wilberforce, M.D. The Weighing Machine [in Diagnosis and Treatment].
 MORRIS, J. E., M.D. Influence of the Bacillary Theory of Tuberculosis on the Treatment of Phthisis.
 MYTON, Seymour, M.D. On the Connection between Chlorosis and Gastric Ulcer.
 ROBERTSON, T. W., M.D. Goitrous Dyspnoea.
 ROBERTSON, J. W., M.D. On the Pathology and Treatment of Pneumonia.
 WEST, Samuel, M.D. On the Treatment of Diabetes Mellitus by Uranium Nitrate.

B. SURGERY.

Central Room, Second Floor—Conjoint Examination Hall.

President: Sir WM. MAO CORMAC, F.R.C.S. Vice-Presidents: J. BRYANT, F.R.C.S.; G. N. MACNAMARA, F.R.C.S.; REGINALD HARRISON, F.R.C.S.; A. WILLETT, F.R.C.S.; Sir W. STOKES, M.D.; MAYO ROBSON, F.R.C.S. Honorary Secretaries: J. D. HARRIS, M.R.C.S., 45, Southernhay, Exeter; J. BLAND SUTTON, F.R.C.S., 48, Queen Anne Street, W.; A. MARMADUKE SHEILD, F.R.C.S., 4, Cavendish Place, Cavendish Square, W.

The President will make some introductory remarks, in which he will refer to the Effects produced by Modern Rifle Bullets on the Human Body.

The following subjects have been selected for discussion:

1. The Diagnosis and Treatment of Fractures of the Upper third of the Femur, including the Neck. To be introduced by Sir William Stokes, M.D. The following gentlemen have intimated their intention of taking part in the discussion:

Professor E. H. Bennett, M.D. (Dublin); Thomas Bryant, F.R.C.S. (London); Professor Chiene, M.D. (Edinburgh); H. H. Clutton, F.R.C.S. (London); J. Ward Cousins, M.D., F.R.C.S. (Portsmouth); Davies Colley, F.R.C.S. (London); Damer Harrison, F.R.C.S. (Liverpool); Sir George Murray Humphry, M.D., F.R.S. (Cambridge); Mansell Moulin, F.R.C.S. (London); Howard Marsh, F.R.C.S. (London); Professor MacEwen, M.D., F.R.S. (Glasgow); Rushton Parker, F.R.C.S. (Liverpool); Mayo Robson, F.R.C.S. (Leeds); Thos. Sinclair, M.D. (Belfast); F. A. Southam, F.R.C.S. (Manchester); Greig Smith, M.B. (Bristol); A. Willett, F.R.C.S. (London).

2. The Surgical Treatment of Cysts, Tumours, and Carcinoma of the Thyroid Gland and Accessory Thyroids. To be introduced by H. Tretham Butlin, F.R.C.S. (London). The following gentlemen have intimated their intention of taking part in the discussion: Professor Annandale, F.R.C.S. (Edinburgh); James Berry, F.R.C.S. (London); Thos. F. Chavasse, M.D. (Birmingham); Kendal Franks, M.D. (Dublin); Damer Harrison, F.R.C.S. (Liverpool); Victor Horsley, F.R.S. (London); Bowreman Jessett, F.R.C.S. (London); C. B. Keetley, F.R.C.S. (London); Professor Kocher (Bern); Dr. Kummer (Geneva); Professor W. MacEwen, M.D. (Glasgow); Rutherford Morison, F.R.C.S. (Newcastle-on-Tyne); James Murphy, M.D. (Sunderland); Mayo Robson, F.R.C.S. (Leeds); W. G. Spencer, F.R.C.S. (London); Sir William Stokes, M.D. (Dublin); Charters Symonds, M.D. (London).

The following papers have been announced:

ANDERSON, William, F.R.C.S. Three Cases of Sacral Hernia of the Sigmoid Flexure through the Left Inguinal Canal, with Anatomical Specimen.
 BROWNE, B. Buckton, M.R.C.S. A Hitherto Undescribed Locality in the Male Urinary bladder where a Stone may lie and elude contact with any Instrument introduced through the Urethra.
 CHAVASSE, Thos. F., M.D. A Successful Case of Removal of the Entire Uppor Lip for Injury by Brier's Method.
 CREYK, Watson, F.R.C.S. On Operations for Malignant Disease of the Pharynx and Naso-pharynx, with Cases.
 FRANKS, Kendal, M.D. On Movable Kidney.
 HORSLEY, Victor, F.R.S. The Results of Operative Treatment of Injury or Disease of the Cervical Vertebrae.
 KESKID, Brigade Surgeon-Lieutenant-Colonel D. F., M.D. Rhinoplasty in India (Lancet Demonstration).
 KEETLEY, C. B., F.R.C.S. On Thirty Cases of Osteotomy of the Hip, with Cases.
 LOCKWOOD, C. B., F.R.C.S. On the Treatment of Hydrocele by Incision.
 MARSH, Howard, F.R.C.S. The Pathology and Clinical History of some Rare Forms of Bony Aneurysms.
 MURPHY, J. B., M.D. (Chicago). Peritonitis.
 MURPHY, James, M.D. On the Importance of Operating Early where an Operation is required in Abdominal Disease.
 PAGER, Stephen, F.R.C.S. Two Cases of Suppurating Hydatid of the Liver drained through the Chest Wall.
 RONSON, A. W., Mayo, F.R.C.S. A Series of Cases of Colectomy.

C. OBSTETRICS AND GYNECOLOGY.

Large Theatre—King's College.

President: Sir WM. PRIESTLEY, M.D. Vice-Presidents: A. R. SIMPSON, M.D.; J. WATT BLACK, M.D.; Sir FRANCIS LAKING, M.D.; J. KNOWSLEY THORNTON, M.B.; W. J. SINCLAIR, M.D.; M. HANDFIELD-JONES, M.D. Honorary Secretaries: W. S. A. GRIFFITH, M.D., 96, Harley Street, W.; A. H. F. BARBOUR, M.D., 4, Charlotte Square, Edinburgh; W. B. DAKIN, M.D., 57, Welbeck Street, W.

The following subjects have been selected for discussion:

Wednesday, July 31st.—The Aseptic and Antiseptic Precautions to be Observed in Private Midwifery Practice, to be introduced by G. E. Herman, F.R.O.P.

Friday, August 2nd.—The Early Diagnosis of Malignant Disease of the Uterus, and the Treatment by Partial or Total Excision, to be introduced by J. Knowsley Thornton, M.B.

D. PUBLIC MEDICINE.

Lower Hall—Exeter Hall.

President: ERNEST HART, D.O.L. Vice-Presidents: J. SPOTTISWOOD CAMERON, M.D.; C. H. W. PARKINSON, M.R.C.S.; WM. COLLINGRIDGE, M.D.; LOUIS C. PAPKES, M.D.; P. BOOBYER, M.D.; JOHN C. THRESH, M.D. Honorary Secretaries: C. E. PAGE, M.R.C.S., Town Hall, Salford; REGINALD DUDFIELD, M.B., Sanitary Department, Vestry Hall, Harrow Road, Paddington, W.; F. W. CLARK, M.B., Lowestoft.

The work of the Section will be inaugurated by an address from the President on Waterborne Diseases.

The regular business of the Section will commence each day with a formal discussion by gentlemen who have been invited to open the debates. The subjects selected are as follows:—

Wednesday, July 31st.—The Regulation of the Slaughter of Animals for Human Food and the Inspection of Animals before and during Slaughter. Opener: T. M. Legge, M.D.

Thursday, August 1st.—Hospital Isolation, House Quarantine, and Disinfection. Opener: P. Boobyer, M.D.

Friday, August 2nd.—The Insecurity of Tenure of Extra-Metropolitan Medical Officers of Health under the Public Health Act, 1875. Opener: E. A. Whitelegge, M.D.

At the conclusion of the discussion of each day papers will be read, selected from the following, as time and opportunity may allow: On the Diagnosis of Doubtful Cases of Diphtheria and the Use of Bacteriology for that Purpose; On the Ventilation of Sewers; The Destruction of Town Refuse by Heat; The Overcrowding of Houses on Land; The Extension and Limitation of the Schedule of Diseases for Notification; Enteric Fever as an Infectious Disease; The Prevention of Milk Epidemics; Hospital Accommodation by the Use of Sheds; Meteorology in Relation to Disease; The Desirability of Appointing Medical Men as Registrars of Births and Deaths. Some of the preceding titles are tentative, as the authors have not as yet definitively decided thereon.

Endeavours are being made to arrange excursions to various places likely to interest those engaged in sanitary work. An offer has been received to practically demonstrate the method of rendering horses immune to diphtheria.

Further details, with full information as to titles of papers, names of speakers, etc., will be announced later. All communications on the business of the Section should be addressed to Mr. Reginald Duffield, M.A., M.B., 19, Blomfield Road, Maida Vale, W.

E. PSYCHOLOGY.

East Wing Room, Second Floor—Conjoint Examination Hall.

President: W. J. MICKLE, M.D. *Vice-Presidents:* G. H. SAVAGE, M.D.; T. CLAYE SHAW, M.D.; D. NICOLSON, M.D.; HENRY RAYNER, M.D.; J. G. McDOWALL, M.D.; LIONEL A. WEATHERLY, M.D. *Honorary Secretaries:* JAMES CHAMBERS, M.D., 99, Harley Street, W.; T. SLYMOOR TUBE, M.B., 37, Albemarle Street, W.; JAMES TAYLOR, M.D., 34, Welbeck Street, W.

The President will open the Section with an Address on the Brain, on Wednesday, at 10 A.M.

A discussion has been arranged to take place on each day, namely:

Wednesday, July 31st.—On the Treatment of Melancholia, introduced by Henry Rayner, M.D.

Thursday, August 1st.—On Insanity, in Relation to Criminal Responsibility, introduced by H. Maudsley, M.D.

Friday, August 2nd.—On Epilepsy, and its Relation to Insanity, introduced by W. R. Gowers, M.D.

The following papers have been announced:

BOND, C. H., M.D. The Relation of Diabetes to Insanity.

CAMPBELL, A. W., M.D. A Comparison of the Breaking Strain of Ribs in the Human and Insane.

HEAD, H., M.D. Mental Symptoms in Relation to Bodily Diseases in the Brain.

MANN, A. I.R.C.P. Mental Symptoms in Relation to Exophthalmic Goitre.

RYNOLD, E. H., M.D. Mental Symptoms of Bodily Diseases.

SAVAGE, G. H., M.D., and CHARLES MARCIE, M.D. Insanity in Conduct.

SHAW, JAMES, M.D. The Early Symptoms of Insanity.

SHOOTER, G. E. M.D. Operative Treatment of Idiocy.

SHOOTER, Percy, M.D. Voluntary Disorders in Angina.

WEATHERLY, L. A., M.D. The Law in Relation to Single Patients.

F. PHYSIOLOGY.

Physiological Laboratory—King's College.

President: DAVID FERRIER, M.D., F.R.S. *Vice-Presidents:* E. E. KLIN, M.D., F.R.S.; WM. STIRLING, M.D.; DR BURGESS BROWN, M.D.; J. HENRY HAYCRAFT, M.D. *Honorary Secretaries:* C. S. SHERRINGTON, M.D., F.R.S., Brown Institution, Wandsworth Road, S.W.; E. H. STARLING, M.D., 14, Grosvenor Road, S.W.

A discussion on the Mechanics of the Cardiac Cycle will be introduced by Professor Havercraft and D. Paterson, M.D.

The following papers have been announced:

BAYLISS, W. M., B.A., B.Sc., and Professor L. HILL. The Physics of the Cerebral Circulation.

BAYLISS, W. M., B.A., B.Sc., and E. H. STARLING, M.D. A New Method of Studying Vasomotor Changes.

BURGESS, Professor of Burgh, M.D. On the Equipment of an Experimental Laboratory, with Exhibition of Apparatus.

BRODIE, T. GREGOR, M.D. The Work of Muscle. Decomposition Products from Gelatine and Collagen.

CAMPBELL, Harry, M.D. The Resistance which the Capillaries offer to the Blood Flow.

ECCLES, Symons, M.B. The Incidence of Leucocytes in the Urine in Health and Disease.

EDMOND-GIBSON, F. W., M.D. On the Perception of Luminosity at Different Parts of the Retina.

HALLIDAY-KTON, Professor, M.D., F.R.S. Nucleo-albumina.

HARLEY, Vaughan, M.D. *Report on a Museum of Food.*

HENDER, William, M.D. Experiments relating to the Functions of the Spleen.

LEATHERS, T. B., F.R.C.S. On the Interchange of Fluid between the Blood and the Tissues.

PERRIN, M. A., M.B. The Physiology of Heat Regulation.

PICKERING, J. W., M.D. Intravascular Coagulation produced by Synthesised Protoid-like Substances.

RANDALL, W., L.R.C.P. Mechanical Coagulation of Proteids.

STEWART, Professor G. N. Further Researches on Circulation Time.

STOKVIS, Professor. The Influence of Sugar on Muscular Work.

TURNER, W. Aldren, M.D. (1) The Results of Lesions of the Tuberculum Rolandi. (2) The Results of Section of the Trigeminal Nerve and the Consequent Degenerations.

Communications have also been promised by Professor Allen, Dr. Haldane, Dr. Paterson, and others.

G. ANATOMY AND HISTOLOGY.

Chemical Theatre—King's College.

President: HENRY MORRIS, F.R.C.S. *Vice-Presidents:* A. MACALISTER, M.D., F.R.S.; W. J. WALSHAM, F.R.C.S.; A. H. YOUNG, F.R.C.S.; B. O. A. WINDLE, M.D.; G. H. MAKINS, F.R.C.S.; A. W. HUGHES, F.R.C.S. *Honorary Secretaries:* F. G. PARSONS, F.R.C.S., St. Thomas's Hospital, S.E.; C. B. LOCKWOOD, F.R.C.S., 19, Upper Berkeley Street, W.

The following subjects have been selected for discussion:—

Wednesday, July 31st.—Art in its Relation to Anatomy, to be opened by Professor William Anderson, F.R.C.S., Joint Lecturer on Anatomy at St. Thomas's Hospital, Professor of Anatomy in the Royal Academy of Arts.

Thursday, August 1st.—The Development and Structure of the Placenta, to be opened by Professor A. H. Young, M.B., F.R.C.S., Professor of Anatomy at Owens College, Manchester.

Friday, August 2nd.—The Topographical Anatomy of the Abdomen, to be opened by Professor A. Thomson, M.A., Professor of Anatomy at Oxford University.

The following papers have been announced:—

GRIFFITHS, J., M.A., F.R.C.S. On the Anatomy of the Genito-urinary Apparatus in the Pig and Boar, with Remarks on the Effects of Castration.

HIGGINS, H., M.R.C.S. On the Mechanism of the Knee.

KEITH, A., M.D. On Synostosis of the Mesosternum to the Transsternum in Man and Anthropoid, considered as to its Prevalence among them and its Value as Evidence of their Genetic Relationship.

KENT, A. F. Stanley, M.A. On the Histology of the Generative Organs in a Hermaphrodite Dog.

PATERSON, Professor A. M., M.D. On the Position of the Kidneys.

PAYNE, J. F., M.D. On an English Anatomical Manuscript of the 16th Century. (Some old anatomical works will also be exhibited.)

ROBINSON, A., M.D. Demonstration of the Structure of the Placenta in Carnivora and Rodentia.

SMITH, T. Manners, B.A., M.R.C.S. (1) On some points in the Anatomy of Three Symmetrical Monsters; (2) Notes upon the Supernumerary Elements of the Embryonic Hand and Foot.

WINDLE, Professor. Note on the Eustachian Tube.

H. PATHOLOGY AND BACTERIOLOGY.

South Room, Ground Floor—Conjoint Examination Hall.

President: SAMUEL WILKS, M.D., F.R.S. *Vice-Presidents:* J. M. FORBES, M.D.; J. F. GOODHART, M.D.; SIDNEY COUPLAND, M.D.; R. SAUNDY, M.D.; W. WATSON CHEYNE, F.R.C.S.; ANTHONY A. BOWLEY, F.R.C.S. *Honorary Secretaries:* S. G. SHATTUCK, F.R.C.S., St. Thomas's Hospital, S.E.; H. D. ROLLISTON, M.D., 13, Upper Wimpole Street, W.

The work of the Section has been arranged as follows:

Wednesday, July 31st.

10 A.M.—Introductory Remarks by the President.

10.30 A.M.—Demonstration of the Malaria Parasite by P. Manson, M.D. (Illustrated by Lantern Slides.) A discussion will follow, in which it is hoped the following will take part: Professor Crookshank; A. A. Kanthack, M.D.; G. Thin, M.D.

11.15 A.M.—A. Foxwell, M.D., on Exophthalmic Goitre; G. R. Murray, M.D., Some Results of Thyroidectomy.

12.30 P.M.—Papers on Cancer and other New Growths: R. Hewlett, M.D., On the Chemistry of Carcinoma and Sarcoma; D'Arcy Power, F.R.C.S.; H. Snow, M.D., The Insidious Marrow Infection of Breast Carcinoma; G. Thin, M.D.; W. Roger Williams, F.R.C.S., On Uterine Neoplasms and their relative frequency.

1.45 P.M.—A. K. Parsons, M.B., Specimen of Larynx from case of Typhoid Fever.

Thursday, August 1st.

10 A.M.—Discussion on Neuritis. Introduced by S. J. Sharkey, M.D. The following have promised to read papers or to join in the discussion: W. Gordon, M.D.; F. W. Mott, M.D.; W. M. Ord, M.D.; Professor Trevelyan, M.D.; Russell Wells, M.B.; W. H. Wilson, M.B.

11.30 A.M.—Discussion on Vaccinia and Variola. Introduced by S. A. M. Copeman, M.D. It is hoped that T. D. Acland, M.D.; S. Coupland, M.D.; Professor Crookshank, M.B., and others will take part in the discussion.

12.30 P.M.—Discussion on Pernicious Anæmia. Paper by W. B. Ransom, M.D. S. A. M. Copeman, M.D., and W. Hunter, M.D., will speak.

1.15 P.M.—Paper by Professor Adami: The Effect of the Reactions of Media upon the Pathogenic Properties of Bacteria.

1.40 P.M.—Paper by A. G. Auld, M.D., on Hematogenous Jaundice.

Friday, August 2nd.

10 A.M.—Discussions on Lymphadenoma. Introduced by W. G. Spencer, F.R.C.S. The following have intimated their intention to take part in the discussion: W. J. Fenton, M.B.; H. Morley Fletcher, M.D.; R. M. Leslie, M.B.; A. A. Kanthack, M.D.; C. A. Morton, F.R.C.S.; G. N. Pitt, M.D.; D'Arcy Power, F.R.C.S.; H. Snow, M.D.; G. Thin, M.D.; Claud Wilson, M.D.

11.30 A.M.—Papers on Leprosy. By P. Abraham, M.D.; G. Thin, M.D.

12 noon.—Professor Babes.

12.15 P.M.—Professor Crookshank on Actinomycosis.

12.30 P.M.—R. Hewlett, M.D.—(1) The Diazo Reaction in Typhoid Fever, (2) On Experimental Tetanus; R. Hewlett, M.D., and St. Clair Thomson, M.D.—On the Fate of Micro-organisms in Inspired Air.

1.30 P.M.—F. R. Walters, M.D.—Pulmonary Hypertrophic Osteo-arthritis.

A. McFadyen, M.D., and R. Hewlett, M.D., will exhibit Cultures and Bacteriological Specimens.

The Secretaries venture to ask gentlemen who intend to show microscopic specimens to let them know the number of microscopes (and the powers) necessary to illustrate their papers, as this will be limited; and also to state whether the use of a lantern is required.

A separate room will be provided for the exhibition of microscopical and other specimens; lantern demonstrations will be given in the meeting-room.

L. OPHTHALMOLOGY.

Large Committee Room, Ground Floor—Conjoint Examination Hall.

President: H. POWER, F.R.C.S. Vice-Presidents: D. ARGYLL ROBERTSON, M.D.; W. A. BRAILEY, M.D.; G. ANDERSON CRITCHETT, M.A., F.R.C.S. Edin.; W. ADAMS FROST, F.R.C.S.; A. EMERY JONES, M.D.; A. H. BENSON, M.B. Honorary Secretaries: R. W. DOYNE, F.R.C.S., Kilerone, Oxford; E. TREACHER COLLINS, F.R.C.S., 54, Wimpole Street, W.; W. T. HOLMES SPICER, F.R.C.S., 47, Welbeck Street, W.

The following subjects have been selected for discussion:

1. On Certain Rare Cases of Recurrent Ophthalmia. Opened by E. Fuchs (Vienna). The affection occurs in adults; it begins with conjunctival and ciliary injection, general or limited, myosis, slight transient myopia, with oedema of the lids in some cases, and occasionally vesicles on the cornea. The duration varies from twenty-four hours to a few days, and recurrence takes place at varying intervals. It is probably anæsto-neurotic in its origin.

2. On the Diagnosis of Orbital Growths. Opened by H. R. Swanzy, F.R.C.S. (Dublin), and Panas (Paris).

3. On the Question of Operating in Chronic Glaucoma. Opened by E. Nettleship, F.R.C.S.

The following gentlemen will take part in the discussions: Messrs. Fuchs, Panas, Swanzy, Nettleship, Galezowski, Hirschberg, Gayet, Meyer, Juler, Lawford, Spencer Watson, Drake-Brockman, Glascock, Mackinlay, Little, Snell, Adams Frost, Critchett, Berry, Griffith, Hartridge.

The following papers have been announced:

BRADSHAW, W. M., M.R.C.S. On the Question of Latent Hypermetropia in the Visual Examination of Candidates for the Public Services.

BENSON, A. H., F.R.C.S. Accompanying with Ocular Complications.

BERRY, G. A., F.R.C.S. On Injection of Chlorine Water into the Vitreous.

FUCHS, Professor E. A New Theory of Erythropsia.

GRIFFITH, John, F.R.C.S. (Title not yet received).

HARTIDGE, G., F.R.C.S. Concomitant Strabismus.

LAW, Charles, L.R.C.P. Cases of Pterygium and Essential Shrinkage of the Conjunctiva.

Papers have also been promised by Messrs. McGillivray, Snell, Edridge-Green, and Juler.

There have also been promises of Specimens for the Museum.

J.—DISEASES OF CHILDREN.

Theological Class Room—King's College.

President: JOHN H. MORGAN, F.R.C.S. Vice-Presidents: W. B. CHEADLE, M.D., F.R.C.P.; F. A. SOUTHAM, F.R.C.S.; H. HANDFORD, M.D.; W. ARBUTHNOT LANE, M.S., F.R.C.S.; A. FOXWELL, M.D., F.R.C.P.; D'ARCY POWER, F.R.C.S.

Secretaries: DAWSON WILLIAMS, M.D., F.R.C.P., 25, Old Burlington Street, London, W.; HUGH R. JONES, M.D., 58A, Grove Street, Liverpool; HERBERT F. WATERHOUSE, F.R.C.S., 81, Wimpole Street, London, W.

The following discussions have been arranged:

a. Congenital Syphilitic Manifestations in Bones and Joints, to be opened by the President of the Section, John H. Morgan, F.R.C.S. Howard Marsh, F.R.C.S., H. H. Clutton, F.R.C.S., Anthony Bowlby, F.R.C.S., Robert Jones, F.R.C.S. (Liverpool), H. B. Robinson, M.D., and Leopold Hudson, F.R.C.S., intend to take part in the discussion, and O. A. Ballance, F.R.C.S., Frederic Eve, F.R.C.S., and H. Stansfield Collier, F.R.C.S., will contribute a series of cases.

b. On the Nervous Sequelæ of Acute Infectious Diseases in Children, which will be introduced by H. Handford, M.D. (Nottingham), and discussed by W. R. Gowers, M.D., F.R.S., Thomas Barlow, M.D., W. B. Cheadle, M.D., Jules Comby, M.D., (Paris), Professor v. Ranke (Munich), E. Robertson, M.D. (Liverpool), James Taylor, M.D., William Hunter, M.D., H. B. Donkin, M.D., T. More Madden, M.D. (Dublin), Fletcher Beach, M.B., F. W. Mott, M.D., Montagu Murray, M.D., W. S. Colman, M.D., and Dawson Williams, M.D.

c. On the Treatment of Hernia in Children, to be introduced by Rushton Parker, F.R.C.S. (Liverpool). Sir William Stokes, M.D., Ward Cousins, M.D., F.R.C.S. (President of Council), Professor William Macewen, F.R.S. (Glasgow), Professor Chiene (Edinburgh), Mitchell Banks, F.R.C.S. (Liverpool), W. Alexander, F.R.C.S. (Liverpool), F. A. Southam, F.R.C.S. (Manchester), Jordan Lloyd, F.R.C.S. (Birmingham), J. Macready, F.R.C.S. (London), D'Arcy Power, F.R.C.S., W. Arbuthnot Lane, M.S., F.R.C.S., C. B. Lockwood, F.R.C.S., H. P. Symonds, F.R.C.S. (Oxford), Herbert Waterhouse, F.R.C.S., George Heaton, M.D. (Birmingham), Damer Harrison, F.R.C.S. (London), W. G. Black, F.R.C.S. (Newcastle), and Reginald H. Lucy, F.R.C.S. (Plymouth), intend to take part in this discussion.

d. Doses of Various Remedies suitable for Children at the Several Ages, to be introduced by J. Kingston Barton, M.B.C.P., D. J. Leech, M.D. (Manchester), J. Mitchell Bruce, M.D., H. H. Donkin, M.D., A. Foxwell, M.D. (Birmingham), N. J. Tirard, M.D., Neville Wood, M.R.C.P. (London), and T. More Madden, M.D. (Dublin), intend to take part in this discussion.

The following papers have been announced:

BALLANTYNE, J. W., M.D. (Edinburgh). The Relation of Certain Diseases of Infancy to Antenatal Anatomy and Physiology.

BARTON, J. Kingston, M.R.C.P. (London). The Relation between the Foods of Early Life and the Condition of the Teeth in Youth and Early Adolescence.

CARR, J. Walter, M.D. A Protest against the use of the term "Consumptive Bowels."

CAUTLEY, Edmund, M.D. On the Value of Trephining in Tuberculous Meningitis.

COMBY, Dr. J. (Paris). The Non-pathogenic Streptococci and Staphylococci of the Throat in Children.

EVE, Frederic, F.R.C.S. 1. Spina Bifida cured by Excision of Sac. 2. Congenital Dislocation of Shoulder backward treated by Operation.

GARROD, Archibald E., M.D., F.R.C.P., and FLETCHER, Morley, M.D. On the Maternal Factors in the Causation of Rickets.

GIBBONS, R. A., M.D. On Renal Colic in Infants.
GRATTAN, Nicholas, F.R.C.S.I. (Cork). Demonstration of Otolithic
HANDFORD, Henry, M.D. (Nottingham). A Case of Erb's Paralysis following
Enteric Fever.
LLOYD, Jordan, F.R.C.S. On Nephrectomy in Children.
LOCKWOOD, C. H., F.R.C.S. Hernia of the Ovary in an Infant with Torsion
of the Testis.
LUCY, Reginald H., F.R.C.S. (Plymouth). The Causes of Hernia in
Children.

THOMAS SMITH, Telford, M.D. (Royal Albert Asylum, Lancaster). The
After-History of Two Cases of Craniotomy.

It is proposed also to arrange for the demonstration of
cases of interest; among these will be:

CLARK, J. Jackson, M.B. (London). Congenital Syphilis with Ulcera-
tion of Tongue.

MORGAN, J. H., F.R.C.S. (President). A Series of Cases of Excision and
Evulsion of the Knee-joint.

K. OTOTOLOGY.

Room 22 - King's College.

President: Sir W. DALRY, F.R.C.S. Vice-Presidents:
CHARLES WARDEN, M.D.; G. P. FIELD, M.R.C.S.; E.
CRESSWELL BAKER, M.B.; J. DUNDAS GRANT, M.D.; EDWARD
LAW, M.D.; O. A. BALANCE, F.R.C.S. Honorary Secretaries:
O. E. L. B. HUDSON, F.R.C.S., 16, Harley Street, W.; G. O.
WILKIN, L.R.C.P., 30, Weymouth Street, W.

Thursday, August 1st.—Discussion on Cerebral Complica-
tions in relation to Middle Ear Disease. Opened by Professor
Macewen, M.D., C.M., F.R.S., LL.D., Regius Professor of Sur-
gery, University of Glasgow.

The Section has also arranged to hold a discussion on the
the Treatment of Nerve Deafness. Particulars of this will be
announced later.

Papers will be contributed and Specimens exhibited by the
following amongst others:

COBBINS, J. Ward, M.D., F.R.C.S. On the Use of Artificial Tympanic
Membranes.

GUTH, Professor. On a not yet described Form of Rotatory Sensation in
Patients suffering from Labyrinthine Disease.

JONES, Carmalt, F.R.C.S. On Turbinitis in Cases of Deafness and
Tinnitus Aurium.

LARK, Richard, F.R.C.S. On the Anatomical Connections of the Tympanic
Membrane, with a few Remarks on their Pathological Importance.
Specimens will be exhibited to illustrate this paper.

METCALVE, George, M.B., will show a Portable Electric Light Battery and
Laryngoscope.

SCATLIF, J. M. E., M.D. On the Use of the Pneumatic Speculum in the
Treatment of Diseases of the Ear.

L. PHARMACOLOGY AND THERAPEUTICS.

East Wing Room, Ground Floor—Conjoint Examination Hall.

President: Sir WILLIAM ROBERTS, M.D., F.R.S. Vice-
Presidents: J. TALFOURD JONES, M.B.; T. LAUDER BRUNTON,
M.D., F.R.S.; J. MITCHELL BRUCE, M.B.; W. HALE WHITE,
M.D.; DONALD MACALISTER, M.D.; M. McHUGH, M.B.
Honorary Secretaries: VAUGHAN HARLEY, M.D., 25, Harley
Street, W.; W. SOLTAT FENWICK, M.D., 10, Devonshire
Street, W.

The following subjects have been selected for discussion:

Wednesday, July 31st.—Discussion upon Serum-therapeu-
tics. Drs. Klein and Washbourn, Professor Fraser, Drs.
Charteris, Tirard, Sidney Phillips, Gayton, Caiger, Boken-
ham, Goodall, Bruce, MacCombie, R. T. Hewlett, and Len-
nox Browne, have promised to speak.

Thursday, August 1st.—Discussion upon the Requirements
of the Profession with reference to the Revision of the *British
Pharmacopoeia*. Dr. Leech, Professors Fraser, Donald Mac-
Alister, and Bradbury, Drs. Page, Spender, Hale White, Tal-
fourd Jones, Charteris, W. Carter, O. Pearson, Tirard, Neville
Wood, James Oliver, H. G. Lya, Kinsey-Morgan, W. Arm-
strong, and Ralph Stockman have promised to speak.

The following papers have been announced:

ANDERSON, Professor. Use of Alternating Currents of High Frequency.

ANDERSON, W. M. R. A. The Therapeutics of Rheumatoid Arthritis.

BERNARD, T. J., M.B. B.S. The Therapeutics of Rheumatoid Arthritis.

CAULFIELD, E. M.D. The Therapeutic Action of Foods in Diseases of Children.

CHURCHILL, F. M.D. The Therapeutic Value of Massage.

CHURCHILL, F. M.D. The Waters of Weymouth Spa.

COTTE, Robert, M.B. B.S. The Waters of Weymouth Spa.

DUNN, Thomas, M.D. The Treatment of Epilepsy.

FARLEY WILSON, R. M.B. The Waters of Loughborough.

FENWICK, W. SOLTAT, M.D. Intestinal Anæsthesia.

FRASER, M.D. The Waters of Strathpeffer Spa.

GORDON, F. W. M.B. and HARLEY, Vaughan, M.D. Action of Piper-
azine on the Acid in the Urine.

HARLEY, Vaughan, M.D. (Title of paper not received.)

HARRIS, Vincent, M.D. Crystalline in Pulmonary Disease.

HIDE, Samuel, M.D. The Waters of Buxton.

ILLINGWORTH, C. R., M.D. Tobacco, Tobacco, etc., their Uses and
Abuses.

MYSTLE, A. S., M.D. The Hæmorrhagic Waters.
OLIVER, George, M.D. Therapeutic Uses of Suprarenal Gland.
OVEREND, Walker, M.B. Therapeutic Value of Arsenic and Bismuth in
Chorea.

PHILLIPS, C. D. F., M.D. The Pharmacological Action of Bismuth.

ROSENDAL, H. V., M.D. (Title not yet received.)

SHARP, Gordon, M.B. The Mydriatic Group.

SNOW, Herbert, M.D. Loretin.

SPENDER, J. Kout, M.B. The Waters of Bath.

SURVEYOR, N. F., M.D., and HARLEY, Vaughan, M.D. Action of
Naphthol and Bismuth Subnitrate as Intestinal Anæsthetics.

TIRARD, Nestor, M.D. Treatment of Chronic Dyspepsia.

WALKER, F. R., M.D. The Pharmacological Use of Cocaine.

WELSFORD, A. G., M.D. Artificial Foods.

WILSON, E. T., M.B. The Waters of Cheltenham.

M. LARYNGOLOGY.

North Room, Ground Floor—Conjoint Examination Hall.

President: FELIX SEMON, M.D. Vice-Presidents: Sir
PHILIP SMYLY, M.D.; W. MACNEIL WHISTLER, M.D.;
F. DE HAVILLAND HALL, M.D.; GERVILLE MACDONALD,
M.D.; SCANES SPICER, M.D.; A. W. SANDFORD, M.D. Honorary
Secretaries: J. MIDDLEMASS HUNT, M.B., 55, Rodney Street,
Liverpool; ST. CLAIR THOMSON, M.D., 23, Queen Anne Street,
W.; E. B. WAGGETT, M.B., 66, Park Street, Grosvenor
Square, W.

The following subjects have been selected for discussion:

Wednesday, July 31st.—The Etiology of Mucous Polyp of
the Nose, introduced by Professor Guye (Amsterdam), Dr.
Luc (Paris), W. B. Tomson, M.B. (Luton), and Dr. McBride
(Edinburgh).

Thursday, August 1st.—The Infectious Nature of Lacunar
Tonsillitis, introduced by Professor B. Fraenkel (Berlin).
Dr. A. Bronner (Bradford), William Hill, M.D., and Dr. J.
Macintyre (Glasgow).

Friday, August 2nd.—The Indications for Early Radical
Operation in Malignant Disease of the Larynx, introduced by
Dr. Bryson Delavan (New York), Mr. H. T. Butlin (London),
and Dr. R. H. Woods (Dublin).

The following members have expressed their intention of
joining in the discussions:

T. Mark Howell, F.R.C.S. Ed., R. Lake, F.R.C.S., L. H. Pegler,
M.D., A. Hodgkinson, M.D. (Manchester), W. Milligan, M.D.
(Manchester), Charles Warden, M.D. (Birmingham), and H.
McKenzie Johnston, M.D. (Edinburgh), on July 31st.
T. Mark Howell, F.R.C.S. Ed., A. Hodgkinson, M.D., Charles
Warden, M.D., and Watson Williams, M.D. (Bristol), on
August 1st. Philip de Santi, F.R.C.S., A. Hodgkinson, M.D.,
and Charles Warden, M.D., on August 2nd.

The following papers have been announced:

BRONNER, A., M.D. Some cases of Diseases of the Larynx and Bronchi
treated by intra-laryngeal injections.

HODGKINSON, Alexander, M.D. (Manchester). (1) A new form of Mag-
nifying Laryngoscope; (2) On the Vibrations of the Vocal Cord; (3) On
Chorditis Tuberosa; (4) On the Function of the Laryngeal Ventricles.

METCALVE, G., M.B. (Newcastle-on-Tyne). Demonstration of a new
powerful and extremely portable Electric Light Battery. (5) A primitive
Electric Light Laryngoscope.

MILLIGAN, William, M.D. (Manchester). Vocal Defects among School
Board Teachers, with special reference to the occurrence of teachers'
nodes.

MORRIS, S., M.D. (Manchester). (1) The Laryngeal Symptoms and
Sequelæ of Influenza. (2) A new form of Laryngoscope.

RUSSELL, J. S. Risdon, M.D. The Representation of Abduction of the
Vocal Cords in the Cerebral Cortex.

DE SANTI, Philip, F.R.C.S. The Operation of Thyrotomy, with a short
account of the cases in which it has been performed at St. Bartholomew's
Hospital during the last fifteen years.

STOKER, George S., M.B. F.R.C.P. An improved method of removing Naso-
pharyngeal Tumours.

The following gentlemen purpose being present and taking
part in the work of the Section: Professor Fraenkel, Professor
Guye, Dr. Luc, Dr. Bryson Delavan, Professor Morris
Schmidt (Frankfurt), Dr. F. H. Bosworth (New York), Dr.
John Mackenzie (Baltimore), Professor v. Sokolowski (War-
saw), Dr. A. Brady (Sydney, N.S.W.), Dr. Walker Downie
(Glasgow), Dr. Hillis (Dublin), Dr. W. Robertson (Newcastle-
on-Tyne), and Dr. Cecil Shaw (Belfast).

N. DERMATOLOGY.

West Wing Room, Second Floor—Conjoint Examination Hall.

President: H. RANBYTH CROCKER, M.D. Vice-Presidents:
McCALE ANDERSON, M.D.; MALCOLM MORRIS, F.R.C.S. Ed.;
J. J. PHIBBS, M.B.; WM. ANDERSON, F.R.C.S.; H. A.
G. HODGKIN, M.B. Honorary Secretaries: J. HARRIS
STOWERS, M.D., 41, Finsbury Square, E.C.; JONATHAN

HUTCHINSON, Jun., F.R.C.S., 15, Cavendish Square, W.
Wednesday, July 31st, 10 A.M., President's Address.

The following subjects have been selected for discussion in the Section:

The Pathology and Treatment of Pruritus, introduced by McCall Anderson, M.D., of Glasgow, and H. A. G. Brooke, M.B., of Manchester.

Diet in the Etiology and Treatment of the Diseases of the Skin, introduced by W. Allan Jamieson, M.D., of Edinburgh, and Walter G. Smith, M.D., of Dublin.

The following papers have been announced:

COTTELL, Edward, F.R.C.S. The Treatment of Syphilis by Injections of Salvarsan.

GALLWAY, James, M.D. Certain Nervous Lesions of the Skin.

HARRISON, A. J., M.B. On Two Cases of Unusual Verruca Negrogenica (with Photographs).

FRY-SMITH, P. H., M.D., F.R.S. Affections of the Skin occurring in the Course of Bright's Disease.

ROBERTS, Leslie, M.D. Treatment and Prognosis of Trichophytosis based on the Physiology of the Trichophyton.

BROWN, J. Herbert, M.D. On a Case of Dermatitis Repens (with Coloured Drawings).

O. ETHICS.

Room B—King's College.

President: W. F. CLEVELAND, M.D. Vice-Presidents: THOMAS BRIDGEMAN, M.B.; J. HUGHES HEMMING, M.R.C.S.; D. B. BALDING, F.R.C.S.; G. PARSONS, M.D.; W. H. AXFORD, M.B.; A. DEMPSEY, M.D. Honorary Secretaries: MAJOR GREENWOOD, M.D., LL.B., 213 Hackney Road, N.E.; T. F. PHARSE, M.D., 12, Norfolk Street, Southsea; HUGH WOODS, M.D., 11, Archway Road, Highgate, N.

Wednesday, July 31st.—General Address by the President. Subjects concerning more particularly the relations of medical men with each other:

1. Intraprofessional Etiquette, introduced by Thomas Garrett Horder, L.R.C.P.

2. Advertising, introduced by George Wm. Potter, M.D.

3. Unqualified Assistants, introduced by George Brown, M.R.C.S., and continued by J. Brindley James, L.R.C.P.

Thursday, August 1st.—The Ethics of Gratuitous and Cheap Contract Practice.

1. Clubs, Medical Aid Societies, and Contract Practice; introduced by R. W. Doyne, F.R.C.S. The discussion will be continued by Hughes Hemming, M.R.C.S., W. Gosse, L.R.C.P., W. A. Elliston, M.D., A. H. Bampton, M.D., W. Newman, M.D., and others.

2. Hospitals and Dispensaries, introduced by Hugh Woods, M.D. Frank Greaves, M.R.C.S., and R. R. Rentoul, M.D., will take part in the discussion.

The Secretaries will be glad to hear from members willing to join in the above discussions.

Friday, August 2nd.—1. Any subject, the discussion of which has not been completed on the two previous days.

2. The reading of any selected papers which do not come under the above heads.

The following papers have been announced:

HERRY, Wm., F.R.C.S. On Contract, Club, and Dispensary Practice.

DICKINSON, W. G., L.R.C.P. Provident Principle in Sickness Attendance.

GLADHILL, J. Grierison, M.B. Barrister-at-Law. Medical Polity.

RICK, William Richardson, M.D. The Public Medical Service and its Relation to Medical Ethics.

STUART, Knowsley, M.D. State Aided & Voluntary Hospitals.

WILLIAMS, A. D., M.D. Changing Relations of the Profession and the Public.

Honorary Local Secretaries:

ANDREW CLARK, F.R.C.S., 71, Harley Street, W.

LEAMHARD OWEN, M.D., 40, Curzon Street, W.

Honorary Local Treasurer:

GEORGE EASTES, M.B., F.R.C.S., 35, Gloucester Terrace, Hyde Park, W.

PROGRAMME OF PROCEEDINGS.

TUESDAY, JULY 30TH, 1895.

9.30 A.M.—Meeting of 1894-95 Council. Council Room, Exeter Hall.

11.30 A.M.—Special Service at St. Paul's Cathedral. Sermon by the Most Rev. His Grace the Lord Archbishop of Canterbury.

2.30 P.M.—First General Meeting. Report of Council. Reports of Committees; and other business. Exeter Hall.

8.30 P.M.—Reception by the Metropolitan Counties Branch.

9 P.M.—General Meeting. President's Address. } In the Imperial

10.45 P.M.—Conversation. } Institute.

WEDNESDAY, JULY 31ST, 1895.

9.30 A.M.—Meeting of 1894-95 Council. Council Room, Exeter Hall.

10 A.M. to 2 P.M.—Meetings of Sections. King's College, Conjoint Examination Hall, and Exeter Small Hall.

3 P.M.—Second General Meeting. Exeter Hall. Address in

Medicine by Sir WILLIAM BROADBENT, M.D., F.R.C.P., Physician-in-Ordinary to H.R.H. the Prince of Wales. Any business

adjourned from First General Meeting at 2.30 previous day.

3.30 P.M.—Musical Promenade of Gardens of Royal Botanic Society.

8 P.M. to 12 P.M.—Illuminated Evening Fete at Gardens of Royal Botanic Society.

9 P.M.—Reception at the Guildhall.

THURSDAY, AUGUST 1ST, 1895.

9.30 A.M.—Meeting of Council. Council Room, Exeter Hall.

10 A.M. to 2 P.M.—Meetings of Sections. King's College, Conjoint Examination Hall, and Exeter Small Hall.

3 P.M.—Third General Meeting. Exeter Hall. Address in Surgery

by JONATHAN HUTCHINSON, F.R.S., F.R.C.S., Consulting Surgeon to the London Hospital. Presentation of the Stewart

Prize to Brigade-Surgeon Lieutenant Colonel L. Douglas Cunningham, M.B., C.I.E., F.R.S.

2.30 P.M.—Dinner of the Association at Queen's Hall, Langham Place.

FRIDAY, AUGUST 2ND, 1895.

10 A.M. to 2 P.M.—Meetings of Sections. King's College, Conjoint Examination Hall, and Exeter Small Hall.

3 P.M.—Concluding General Meeting. Exeter Hall. Address

in Physiology by EDWARD ALBERT SCHAPER, F.R.S., Jodrell Professor of Physiology, University College.

9 P.M.—Conversation at the Royal College of Physicians.

9 P.M.—Conversation at the Royal College of Surgeons.

SATURDAY, AUGUST 3RD, 1895.

Excursions.

Particulars of further Entertainments, open to a limited number of Members only, will be found in the Local Guide.

RECEPTION ROOM

The large hall at King's College will be opened at 12 o'clock noon on Monday, July 29th, and on Tuesday, July 30th, and the following days at 9 o'clock, for the issue of tickets to members and for supplying all necessary information. A reception room for invited foreign guests will be provided next to the large hall. It is particularly requested that members on their arrival will at once proceed to the reception room, enter their names and addresses, and obtain their tickets and Daily Journals containing programme, inquire for letters and telegrams, consult the list of lodgings, hotels, etc.

Only members of the British Medical Association, invited guests and accredited strangers will be allowed to attend the general meetings or the meetings of sections. Members and guests will be required to show their cards, which must be obtained and signed for at the Reception Room. Invited guests will be required to show their invitation cards upon entrance to any of the general meetings or meetings of sections. Members and guests are therefore earnestly enjoined to take care of their cards of admission, and to note that they are not transferable, and if lost cannot be renewed. Members or guests may take one lady only to any of the entertainments.

Only members and officially invited guests will be admitted to the dinner of the Association.

The Reception Rooms will be opened on Monday, July 29th, at 12 o'clock noon. Tickets for the dinner and excursions will not be issued until Tuesday morning. In applying for tickets members will be required to produce their membership cards to be stamped.

The members' Reception Room is in the large hall of King's College. There is a separate Reception Room for invited foreign guests next to the members' Reception Room, and another for ladies at the Royal Society's Rooms, Burlington House.

The post office and telegraph office are in the Reception Room, King's College. Members are requested to apply for letters and telegrams from time to time.

Members of the Association who intend visiting London during the annual meeting to be held on July 30th, 31st, August 1st and 2nd, are particularly requested to fill up the form in the centre of the JOURNAL, and to stamp and post it, in order that the arrangements may be completed.

NOTICES OF MOTION.

Dr. ARTHUR WELSFORD hereby gives notice that he will move and Mr. J. F. BULLAR will second:

That it is in the interest of the public and of the medical profession that the Council of the British Medical Association should take power

and authority to protect both the individual and collective interests of the medical profession, and that the Council be requested to take such steps as may be necessary to enable it to actively undertake these duties.

Dr. R. R. KANTON hereby gives notice that he will move, and Dr. H. Woods will second:

That as Sections 7 and 8 of the Medical Act, 1886, provide for the election of only five direct representatives to the General Medical Council by the registered medical practitioners resident in the United Kingdom; and as Section 13, subsection 1, Paragraph 2 of this Act provides that the General Medical Council may represent to the Privy Council that it is expedient to confer upon the registered medical practitioners resident in any part of the United Kingdom the power of returning an additional number of direct representatives to the General Medical Council; and as the General Medical Council has, on November, 1886, on November, 1891, and on November, 1892, refused absolutely to make such representation; and as the number of registered medical practitioners has increased from 22,719 in 1876 to 52,064 in 1894, and as we medical practitioners were not given our due and proper number of direct representatives in 1886; and as the registered practitioners constitute all the income of the General Medical Council, by which the Medical Acts are administered, while the twenty universities and colleges represented on the General Medical Council do not contribute any income to it; and as the representatives of the universities and colleges are elected to the General Medical Council by their small convocations, Senates, and Councils, and not by open vote of all their medical graduates only; and as other important councils, having similar but larger duties to the General Medical Council, such as the Councils of the Incorporated Law Societies of England and of Ireland, the Councils of the Pharmaceutical Societies of Great Britain and of Ireland, and the Council of Veterinary Surgeons, consist of direct representatives only, this Association instructs its Council to take immediate steps to have a Bill introduced into Parliament providing that the registered medical practitioners in England and Wales be empowered to elect five additional direct representatives, the practitioners resident in Scotland one additional direct representative, and the practitioners resident in Ireland one additional direct representative to the General Medical Council.

Mr. LAWSON TAIT hereby gives notice that he will move, and Mr. COLIN CAMPBELL will second:

That we, the members of the British Medical Association, while anxious to improve the training and supervision, and, if need be, to support a practical scheme for the registration of medical, surgical, and midwifery nurses, emphatically condemn any proposal which has for its object the formation of a class of medical or surgical or midwifery practitioners other than those recognised under the Medical Act, 1886, as now existing. We protest against the Midwives Registration Bill because it proposes to establish a class of midwifery practitioners who would be very incompletely trained in midwifery, and entirely uneducated in medicine, surgery, and pharmacy—a matter of supreme importance in midwifery practice. We therefore instruct the Council and the Parliamentary Bills Committee to use every means to oppose any Bill which proposes to give to persons registered under it power to conduct, on their sole and independent responsibility, any midwifery practice without the guarantee of a complete curriculum and qualification. That this Association recommends a sum not exceeding £1,000 be expended for the purpose of opposing any such Bill.

June, 1895.

FRANCIS FOWLER, General Secretary.

The Ladies' Reception Committee have organised the following excursions, under the guidance of experts, for the benefit mainly of the wives of members of the Association. Should any lady, however, wish to obtain a ticket for an excursion for her husband it will be possible for her to do so. The number of tickets for each excursion will be strictly limited, and it is mentioned below. The cost of a ticket for each excursion, except for the one to the Cambridge Colleges, will be 1s. Ladies living in London will not be able to obtain tickets till the week of the meeting. Ladies living in the country or abroad may obtain them in advance by writing, and enclosing postal orders, to Mrs. R. Priestley, 81, Linden Gardens, Bayswater, London, W.

1. Giron and Newnham Colleges, Cambridge (40 tickets). The party will be entertained at the two Colleges. Date: Friday, August 2nd.

2. Westfield College, Hampstead (30 tickets). Date: Friday, August 2nd. Tea and coffee will be provided by the College.

3. British Museum. Mr. A. S. Murray will take a party of 15 on two days to the Greek antiquities, and Mrs. Tirard will take a party of 15 on one day to the Egyptian antiquities.

4. St. Paul's Cathedral. The Rev. Canon Gilbertson will take a party of 30 on July 31st.

5. Westminster Abbey. The Very Rev. the Dean of Westminster, Mrs. Murray Smith, and Mr. Weller will respectively take a party of 30 on July 31st, August 1st, and August 2nd. The Royal and other wax effigies in the Abbey will be shown.

6. The Tower of London. The Rev. W. J. Loftie will take a party of 25 on July 31st at 2 P.M. Special orders have been obtained from the Governor of the Tower.

7. National Gallery. Mr. Cosmo Monkhouse and Miss M. K. Bradby will take a party of 12 on July 31st and August 1st respectively.

8. Natural History Museum. Mr. George Murray will take a party of 30 on July 31st at 11.30 A.M.

9. South Kensington Museum. The Director, Mr. Armstrong, will take a party of 12 on July 31st and August 1st, at 2.30 P.M.

SPECIAL CORRESPONDENCE.

PARIS.

Opening of the Health Exhibition.—Piano Playing and Neuroses in Girls.—Laying the Foundation Stone of a New Hospital in Paris.—An Anti-alcohol League.—Hypnotism and Wall making.—General News.

On June 28th the President of the Republic officially opened the Champ-de-Mars Sanitary Exhibition. He was received by M. Brouardel, Dean of the Paris Medical School, and visited all the different sections of the exhibition. The present exhibition is not so important as the one held in 1886. It is divided into five sections, namely: (1) sanitation of dwellings; (2) sanitation of towns; (3) the prophylaxis of contagious illnesses, demography, sanitary statistics, and sanitary science; (4) industrial and professional sanitation.

A corresponding member of the Paris Academy of Medicine has sent to that learned body a memoir in which he maintains that the numerous cases of chlorosis, neuroses, and neurasthenia observed among young girls is due to learning to play on the piano and the hours devoted to practising. He has drawn up careful statistics from which he concludes that, among 6,000 pupils obliged before attaining the age of 12 to learn to play the piano, nearly 12 per cent. suffer from nervous troubles. The author does not attempt to draw up statistics of the victims among persons who have to listen to their performances.

Mme. Félix Faure, the wife of the President of the Republic, a few days ago laid the first stone of the hospital built by the Association des Dames Françaises in the Rue Michel-Ange, Autenil. As a matter of fact building has been some time in progress, and one pavilion is already finished. Nevertheless the ceremony of laying the stone had not taken place. Mme. Félix Faure, acting as *présidente d'honneur*, threw the handful of salt over the hollow stone containing the medal of the Association and the documents signed by the architect, Mme. Félix Faure, the Countess Foucher du Careil, and Dr. Duchaussoy. The benediction was then given. Dr. Duchaussoy, in his address, stated that ladies not positively embracing the medical profession were with difficulty admitted to the Paris hospitals; they were thus unable to gain the knowledge required of *ambulancières*. The hospital of the Dames Françaises supplied this want. All women could there fit themselves for such duties. According to Dr. Duchaussoy, in Germany there are special hospitals where women receive medical instruction; these exist in every German province. Aristocrats and crowned heads consider it a duty and honour to go through their terms in the hospitals, and become well informed reliable nurses, ready to do their duty in the time of war. Dr. Duchaussoy said it was with the intention of following the good example set by Germany that the hospital was organised. During peace there will be only twenty-four beds, twelve medical cases, twelve surgical; if war breaks out or epidemics threaten the public health, 120 beds will be ready to give relief to the suffering.

At Nîmes a league has been organised to combat the increase of alcoholism. Every class is represented in it. The scheme is to organise a great petition to have "drink legislation" remodelled, and to organise temperance coffee-houses to be used as clubs by the masses.

The Third Chamber of the Civil Tribunal of Lyons has recently given judgment in a case in which the validity of a will was contested on the ground that the testator was under the influence of hypnotic suggestion. Mme. Guindraud, a widow, died, leaving £12,000 to M. and Mme. Jouve. The husband is a magnetiser and a *massor*, and the wife a "somnambulist." Mme. Guindraud has only very distant relations. M. and Mme. Jouve, at Mme. Guindraud's request, lived in her house. Dr. Lacassagne, in his evidence, said it

was evident that Jouve exercised a great influence over Mme. Guindraud, and that he could have suggested to her to make a will in his favour. The court nonsuited the plaintiffs, the will was declared valid, and the defendants remain in possession of Mme. Guindraud's fortune.

The following names of distinguished scientific and medical men will be given to different Paris streets: Trousseau, Charcot, David Ulysse Trélat, Milne Edwards, Jean Baptiste Dumas.

HONG KONG.

The Plague in Hong Kong.—The Plague in Macao.—Cholera in Siam.

No cases of plague have occurred in Hong Kong since the last report sent to the *BRITISH MEDICAL JOURNAL*—now three weeks ago. At that time four cases only were recorded, and they represent the total met with. They were all importations from Macao or the country around. Plague is still prevalent in Macao, but neither in Canton nor in any of the large towns in this neighbourhood has plague occurred. It is now the end of May (29th), the rainy season has set in, and, as by this time last year the plague had reached its maximum, the colony begins to hope that the scourge will not return. The general health of the colony is excellent.

Under the heading of "The Plague in Macao" a paragraph appears in the *JOURNAL* which has just reached us which requires answering. The Governor of Hong Kong had no pressure brought to bear upon him, publicly or privately, to stop immigration from Macao. The step was taken on his own initiative. Further, the unofficial members of the Sanitary Board did not resign on account of any acts of omission or commission on the part of the Government, but upon a mere quibble in connection with the position of the new appointment of medical officer of health. The unofficial members maintain that the officer should be a servant to the Board, whereas the Government wish him to be an independent adviser to the Board and the Government.

In Bangkok and throughout Siam cholera is epidemic. In Saigon and the French provinces of Tongkin cholera, if not epidemic, is very prevalent, and not a few Europeans have died. The condition of the river at Bangkok is filthy. Carcasses of animals float past the shipping in the river in great numbers, and the stench from the banks is abominable. The dead bodies of animals in the river indicate the state of affairs up country. In all cholera epidemics neglect to feed and attend animals is one of the first signs of the intensity of the disease. The death-rate of animals in consequence augments, and, as burial in water is more easily accomplished when labour is scarce than burial in earth, the river is chosen as the easier means. Round the lower reaches of the river, where the population is always most dense, cholera breaks out in consequence, and so the disease progresses.

CORRESPONDENCE.

THE LANCASHIRE AND CHESHIRE BRANCH AND THE MIDWIVES BILL.

SIR.—It is difficult to reason with Dr. Carter. Ignoring facts, he replaces them with the emanations of his own brain, and then calmly argues from the false premises. His "negative fact" has turned out a mare's nest; but he still sticks to the "positive fact"—that the petition lately presented to the General Medical Council was not signed by the officers of the Lancashire and Cheshire Branch.

On June 22nd we pointed out that the petition was "officially" signed, and referred to the minutes of the Council for corroboration of our statement. His reply (June 26th) is characteristic. "Nowhere," he says, "so far as I have been able to discover, is a petition published, with the names of those officers attached to it." One would have thought that any man of scientific pretensions would have taken the trouble to "verify his reference" before rushing into print.

As Dr. Carter is apparently ignorant of the existence of the official "Minutes of the General Medical Council," we

beg to refer you, Sir, to the minutes for May 29th, 1895, App. ii, p. 15, on which you will find the signatures of the Vice President and the General Secretary of the Lancashire and Cheshire Branch appended to the petition together with our own, in exact accordance with the resolution of the Branch, relied on by Dr. Carter in support of his "argument."

Towards the end of his lengthy letter, Dr. Carter apparently begins to feel his ground insecure, and therefore seeks to "hedge"—laying the blame for his inaccuracies on someone else.

One more fact, and we have finished with him. His letter to you is dated June 22nd; on June 17th he was present at the annual meeting of the Lancashire and Cheshire Branch at Liverpool, and heard the General Secretary, in reply to a question, affirm that the petition had been regularly signed and presented; and he sat, still silent, whilst the vote for the expenses of the Committee was passed unanimously. We are, etc.,

WM. HUGH HUGHES,
Chairman,
COLIN CAMPBELL,
Honorary Secretary,
Lancashire and Cheshire Branch Committee.

Manchester, July 2nd.

MIDWIVES' REGISTRATION AND THE MIDWIVES BILL.

SIR.—Dr. Bruce practically states that incorrect medical certificates for death are manufactured on a wholesale scale throughout the country. He implies, moreover, that Mr. Charles Paget, the medical officer of health, publishes in his annual report information which is misleading, and that the whole system of the administration of the Health Department is behind the times. It is of course impossible for me to ascertain how far Dr. Bruce is right about the incorrectness of death certificates, but the statement certainly requires some definite proof before it can be accepted. Now let us see how the borough of Salford is looked after by its medical officer. The staff consists of a chief inspector of nuisances, an assistant inspector, two drainage inspectors, a smoke inspector, an inspector for lodging houses, another for canal boats and workshops, an inspector under the Shop Hours Act and for food and drugs, besides the veterinary department. There are six female health visitors working in the borough under the auspices of the Ladies' Health Society. In all, during 1894, without counting the inspections and visitations of the female health visitors, 33,118 inspections and 29,114 re-inspections of premises of all kinds were made. Under these circumstances it is only fair to believe that the borough is watched in the most efficient manner practicable.

As to puerperal fever, Mr. Paget states "that special inquiries were made in all the cases, but it was not necessary for the Health Department to take any further action than to secure efficient disinfection of premises, bedding, and clothing." As to Dr. Holmes's evidence, which I have studied, if the General Medical Council prefers to base its decision and actions upon such evidence when such valuable reports as those of Mr. Paget are available I can only say that I am sorry for that Council. So far as I can ascertain the Bill is only based upon the authority of a few obstetricians, who have neither given the time nor taken the trouble to ascertain the facts.

It is very easy to assert that practitioners who are at work all over the country neither understand obstetrics nor the conditions and surroundings in which they work, and that medical officers of health are ignorant of the special conditions of their own districts, but I think it would be a matter of some difficulty to bring any evidence to show that such is really the case.—I am, etc.,

Hatfield, July 1st.

LOVELL DRAGE.

SIR.—In the *BRITISH MEDICAL JOURNAL* of June 22nd, you publish a letter from Dr. Smyly, Master of the Rotunda, which seems to indicate that he has fallen into some errors in respect to the Midwives Bill. He regards the definition of the term "midwife," as given therein, as indicating the inten-

tion of the Midwives Institute to obtain for midwives entire freedom from medical supervision. As a matter of fact the definition was drawn up by a Provisional Committee, which led up to the formation of the Midwives' Registration Association, and it was adopted by the Association at its first general meeting on July 3rd, 1893, as a part of its working basis. No midwife had any hand in its drafting. Dr. Smyly, himself a member, I am glad to say, of the Association, has, or should have, adopted the definition in common with the rest of the members as meaning the present anarchical condition of midwives; this is all it means. The Bill is intended to place the midwives under control. The definition is omitted altogether in the amended measure.

Another objection raised by Dr. Smyly is that the Bill does not sufficiently provide against midwives treating cases which are not normal. In the amended Bill a special clause provides against any further misconception on this point.

He also complains that all authority will be centralised in London; but, as a matter of fact, it is not so centralised, nor was it ever intended to be so centralised. But the proposed Board must have an office somewhere, though London is not mentioned even for this purpose.

It would be entirely against the policy of the Midwives' Board to keep the excellent Rotunda midwives from practising in England or Wales; Dr. Smyly is quite mistaken in what he states in this respect.

Perhaps Dr. Smyly would kindly suggest the amendments he desires to see in the present Bill, and they will, without doubt, obtain a fair hearing. As Secretary to the Midwives Bill Committee I will do all I can to get them well discussed, and in any case the authority for them will command respect.—I am, etc.,

Fellows Road, N.W., June 25th.

F. ROWLAND HUMPHREYS.

PERMANGANATE OF POTASSIUM AS AN ANTIDOTE FOR OPIUM POISONING.

SIR.—The article by Dr. William Moor in the *BRITISH MEDICAL JOURNAL* of June 22nd was sent me by a friend who knows my claim to be the first to introduce potassium permanganate as an antidote to opium and morphine poisoning. There are some facts which ought to come under the notice of your readers with respect to this "new" antidote. I introduced acid solution of potassium permanganate as an elegant quantitative test for morphine and cinchona alkaloids in 1877. I recommended solution of potassium permanganate in the year 1884 as an antidote for morphine, opium, and laudanum. Such 1 per cent. solution of potassium permanganate was my legal property prior to the introduction of a 1 per cent. solution into the *Pharmacopœia*. It was brought out for the convenience of workers using my method of oximetry introduced in 1877. I send you herewith a label on which you will see: "As an antidote to opium, morphine, and laudanum the diluted solution may be administered in doses of a wineglassful." This label was printed, together with a scientific pamphlet, by Messrs. Silverlock, Blackfriars Road, more than ten years ago.

As regards the "selective faculty" of potassium permanganate for morphine in the presence of albumen, I found so early as 1877 milk and albumen solutions react on my reagent. In the year 1880 the Belgian Academy appointed Messrs. Janssen and Spring to inquire into my method applied to the estimation of food stuffs. Their report and my papers will be found in the *Bulletin* of the Royal Belgian Academy for 1890 and 1891. Those interested in this subject of estimation of food stuffs by means of acid permanganate should consult *Invention* from 1892, December 10th and 17th, and a long series of articles in the same, from October, 1893, to July, 1894. About fourteen articles may be found in the *Mæd* dealing with my method applied to flour and bread, 1893 to 1895.

Those interested in knowing exactly the reactions of albumen and potassium permanganate, will find them recorded in my pamphlet *Rapid Analysis of Milk*, by the permanganate method. However, when we recognise the fact that probably 60,000 cases of opium or morphine poisoning have occurred since I first published the antidote in 1884, we must confess

that after all we must sometimes risk our lives, as Dr. William Moor has risked his, to secure serious and proper consideration of our convictions.—I am, etc.,

June 26th.

J. BARKER SMITH, L.R.O.P.

URGENT POOR-LAW CASES.

SIR,—I think we must all welcome with great satisfaction the recent action of the Local Government Board in reference to the answer given to the Whitechapel Guardians as regards accidents and sudden cases of illness amongst the poor. According to the orders last issued, the nearest medical man called in will now be able to receive his fee from the guardians, thus preventing delay and possibly death, and unjust comments in the daily press in reference generally to the Poor-law medical officer.—I am, etc.,

J. WICKHAM BARNES,

Honorary Secretary Poor-law Medical Officers' Association.

July 1st.

PROPOSED COMPULSORY INSPECTION AND REGISTRATION OF STILLBORN CHILDREN.

SIR,—In the *BRITISH MEDICAL JOURNAL* of June 29th Dr. Mullins, of Sydney, calls attention to a error which appeared in my remarks on the above subject in the *JOURNAL* of April 6th. You will remember that you considered my "paper" too long, and therefore it was cut down from 18 to 7½ pages. The words in the original manuscript which I sent were: "Dr. Mullins, of Sydney, informs me that in New South Wales, under Section 16 of the Children's Protection Act, 1892, it is enacted that when a stillborn child has been born in a lying-in home, it must not be interred until the certificate of a medical practitioner or of a magistrate is obtained, and that a stillborn child is one born dead after the commencement of the sixth month of pregnancy."—I am, etc.,

Liverpool, June 30th.

R. R. RENTON.

THE ANNUAL MEETING AND SOUTH WALES MEMBERS.

SIR,—Perhaps you will allow me an opportunity of informing the South Wales and Monmouthshire members that the Great Western Railway intend running an excursion train every Monday during the months of July, August, and September, from Swansea, Neath, and Cardiff to London, returning either on the following Saturday or the Saturday week. I have received a promise from the superintendent of the line that he will provide a saloon carriage for the use of medical men who intend travelling by the train leaving Cardiff on Monday, July 29th. It will be necessary for members to give me an early intimation of their intention to travel by this train. It will leave Cardiff about 4.20 p.m.—I am, etc.,

Cardiff, July 2nd.

T. GARRETT HORDER.

CLUBS, MEDICAL AID ASSOCIATIONS, AND CONTRACT PRACTICE.

SIR,—Having been asked to read in the Ethical Section the opening paper on Clubs, Medical Aid Associations, and Contract Practice, I shall be much obliged if those who have personal experiences in these matters, favourable or otherwise, will kindly communicate the facts to me.—I am, etc.,

64, St. Giles's, Oxford, July 2nd.

ROBERT W. DOVSE.

DILATATION OF THE CERVIX.

SIR,—I have read with much interest the article in the *BRITISH MEDICAL JOURNAL* of June 29th, by Dr. Braithwaite, on Dilating the Cervix Uteri. The physiological fact that the cervix is so much more easily dilatable immediately at the end of a menstrual period than that at other times is one of great practical importance, and the thanks of the profession are due to Dr. Braithwaite for laying emphasis on this fact, especially as there is no allusion to it in the textbooks in common use.

I have tried most forms of dilating the cervix of the non-pregnant uterus, including Tait's, Hegar's, and bladed metallic dilators, and have come to the conclusion that the best results can be obtained from a combination of the use of Tait's and Hegar's dilators, though not in the sequence Dr. Braithwaite uses them. The method I have adopted for

¹ Vide *Year Book of Pharmacy* for 1883, and elsewhere.

² Messrs. Williams and Norgate, Covent Garden.

the past twelve months, both in hospital and private practice, has been to put in a laminaria tent at night; and on the following morning, on removing the tent, to proceed with dilatation by Hegar's dilators. The tent, in addition to expanding the cervix so that one may begin with No. 12 or 13 Hegar, softens the tissues and renders the use of Hegar's dilators a much easier and shorter operation.

I have never seen any of the ill-effects Dr. Braithwaite mentions follow the use of a Tait.

I may say that before introducing the tent the vagina is washed out thoroughly, and I endeavour to get a good view of the cervix and to wipe away all discharge. The tents are kept before use in a 5 per cent. solution of carbolic acid in absolute alcohol, and I have not found this impair their expansile power.—I am, etc.,

C. E. FUSLOW, M.D. Lond., M.R.C.P. Lond.

Birmingham, July 2nd.

THE COLONIAL MEDICAL SERVICE AND THE ARMY MEDICAL STAFF.

SIR,—I propose that all appointments to the official Colonial Medical Service be made from officers serving in the Army Medical Staff who are willing to accept such service. Officers accepting colonial service to be placed on a reserve list such as exists in the Royal Engineer service. My reasons for making this suggestion are:

1. There is no competitive examination for colonial appointments, and the days of nomination for such appointments are over.

2. There is no training as to tropical diseases available for young medical officers sent to the colonies in the civil service.

3. If one colony does not suit a young official he may have to resign the service.

By recruiting from the Army Medical Staff officers serving in the colony could accept continuous civil employment there, and they would have benefited by the training of the Army Medical Staff. Up to the end of ten years' service officers could revert to the military service, but after ten years' service they would not be eligible to return to military employment, and would remain in colonial employ. Permanent service in a colony the climate of which suited an officer might be more acceptable than the continuous movements the military service needs; and whatever advantages the colonial service holds out should be first of all offered to those medical men who are serving the State in peace and war in her army. As we have no conscription, I feel sure that service in the Army Medical Staff should be a condition of entry into many branches of Government medical service besides this colonial branch.—I am, etc.,

June 28th.

COLONY.

NAVAL AND MILITARY MEDICAL SERVICES.

THE NAVY.

THE following appointments have been made at the Admiralty:—ARCHIBALD M. KINLEY, FRCS Surgeon, and BENJAMIN H. BRADFORD, FRCS Surgeon, to the *Thetis*, July 2nd; EDWARD W. LUTHER, FRCS Surgeon, and EDWARD T. P. EAMES, Surgeon to the *Thetis*, July 6th.

An examination of naval surgeons who are eligible and may be desirous of qualifying themselves for the rank of Staff Surgeon will be held at HAZARD HALL, S.W., on July 10th. Intention to take part in the examination must be notified to the Inspector-General not later than July 6th.

ARMY MEDICAL STAFF.

SURGEON-CAPIAIN J. E. TRASK has been selected for service with the Egyptian army.

SURGEON-LIEUTENANT H. C. FRENCH who has not yet quite completed one year's service, has been selected for duty with the Coldstream Guards as an attached officer, *vice* Surgeon-Captain M. T. YARR, who has been appointed Physician to the Crown Prince of Siam.

INDIAN MEDICAL SERVICE.

THE Principal Medical Officers of the four commands in India are to have the rank of Surgeon-Major-General.

ARMY MEDICAL RESERVE.

SURGEON-CAPIAIN A. T. WEAR, M.D., 1st Newcastle-on-Tyne Volunteer Artillery (Western Division Royal Artillery), to be Surgeon-Major, July 1st.

SURGEON-LIEUTENANT J. H. MACLEAN, F.R.C.S. Edin., 2nd Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment), to be Surgeon-Major, July 1st.

THE VOLUNTEERS.

THE undermentioned officers have received their commissions, July 2nd: Surgeon-Lieutenant J. H. GIBSON, M.D., 2nd Middlesex Artillery; Surgeon-Lieutenant E. ROSE, 4th Volunteer Battalion the Hampshire Regiment; Surgeon-Captain H. ST. CLAIR-GRAY, M.D., 1st Volunteer Battalion the Hampshire Regiment.

SURGEON-CAPIAIN W. MASON, 1st Cornwall (Duke of Cornwall's Artillery), is promoted to be Surgeon-Major, July 1st.

SURGEON-MAJORS W. WILSON, M.D., and W. FINEW, M.D., 1st Volunteer Battalion the Royal Scots Fusiliers, are promoted to be Surgeon-Lieutenant-Colonels, July 1st.

MR. WILLIAM BALFOUR FERGUSON, M.D., is appointed Surgeon-Lieutenant in the 1st Gloucestershire Engineers (Fortress and Railway Forces, Royal Engineers), and Mr. JAMES TAYLOR, M.D., in the same capacity to the 6th Volunteer Battalion the Gordon Highlanders, both dated July 1st.

VOLUNTEER PROMOTION.

A CORRESPONDENT writes to point out that promotion to brigade-surgeon is governed by Paragraph 65 of the Volunteer Regulations. This paragraph states that the brigade-surgeon is appointed on the recommendation of the brigadier (having first consulted the principal medical officer of the district), submitted through the general officer commanding the district. When appointed he becomes of the rank of lieutenant-colonel, but he need not have held that rank before. He may be promoted from surgeon-major or even surgeon-captain.

THE WAZIRISTAN AND CHITRAL EXPEDITIONS.

THE *London Gazette* of July 2nd contains a general order, dated May 10th, together with a despatch from Lieutenant-General Sir W. B. A. Lockhart, detailing the operations of the Waziristan Field Force; and general orders, dated April 26th and May 10th (three of the latter date), with despatches from Lieutenant-General Sir R. G. Low, regarding the operations of the Chitral Relief Force, which have been received at the India Office from the Government of India.

In giving the details of the services of the officers with the Waziristan Force, Sir William Lockhart says: "Surgeon-Colonel L. D. Spencer, M.D., Indian Medical Service, has most ably administered his department in the field, and I commend the excellent work done by himself and by his officers and other subordinates for very favourable consideration. He has been well supported by all, but I wish to give special prominence to the valuable services of Surgeon-Lieutenant-Colonel J. T. B. Bookley, Indian Medical Service, and Surgeon-Major J. Shearer, M.B., Indian Medical Service."

In the same despatch Surgeon-Lieutenant E. G. Seton, Indian Medical Service, is reported to have received a severe gunshot wound in the left knee.

THE SCOURGE OF INDIA (ENTERIC IN 1885).

BRIGADE-SURGEON-LIEUTENANT COLONEL W. H. CLIMO contributes to the current number of the *Indian Service Magazine* an article headed as above, in which he relates the remainder of Surgeon-Major Perry Marsh, which appeared in May. Dr. Climo restates his two propositions, namely, (a) that since the introduction of short service there has been a marked improvement in the health of the army, both at home and abroad, resulting from causes almost entirely outside the action or control of the Army Medical Department; (b) that so far as India is concerned, there has been during the same period an unusually increasing admission-rate and death-rate from enteric fever of British troops consequent upon both sanitary and medical failure, resulting from regiments having no longer medical officers serving with them. The writer denies the assumption that he advocates a return to the old regimental system. Brigade-Surgeon Climo recommends the appointment of a Special Commission to inquire into and report to Parliament upon (1) the present sanitary condition of Indian cantonments, and (2) their relation to the increasing prevalence and mortality from enteric. He says: "The want of coherence in the department (graphically described by Marsh) affords the strongest reasons for the appointment of such a Commission."

LEAVE IN INDIA.

THE Government of India have decided to grant medical officers leave out of India on the usual conditions—namely, if their services can be spared locally and with the consent of the Principal Medical Officer at Army Headquarters.

HEALTH OF THE ITALIAN ARMY IN TIME OF PEACE.

DURING the period from 1872 to 1892 the average admissions during the seventeen years into the Italian military hospitals and infirmaries was 569 in an average force of 1,000. The average proportion of entries into the hospitals only, according to the different months, were as follows: the maximum in March, a diminution up to July, when it increased; the minimum in November, with an increase in December. The constancy was not great. It is impossible to compare the causes of morbidity in the army with those of the civil population, as the statistics of the civil hospitals are so few. From an analogous study for the German army from 1867 to 1892 it appears that the maximum amount of sickness occurs in January, a diminution from January to June, an increase in July, the minimum in September, and an increase in November. The oscillations of total morbidity, as well as those of the various forms of disease, are as much allied in the civil population as in the military to the season of the year, in the way that this predominates over the other particular influences which determine the disease. The recruits exposed to the same atmospheric influences are taken ill in greater numbers than the older soldiers. During the year the particular conditions of the army have little influence on the development of diseases in comparison with general unhealthy causes. It also appears that traumatic lesions are not more frequent in the German army in time of peace. In Italy also the manifestations and the developments of the various diseases depend principally on the atmospheric conditions of the various seasons, and

that military life can only be a modifier of an ordinary importance. The more numerous oscillations in the canal movements of the seventeen years taken for an estimate must therefore depend on the greater variety and inconstancy of the Italian climate compared to that of Germany.

THE SECRETARY OF STATE FOR INDIA AND THE INDIAN MEDICAL SERVICE.

A CORRESPONDENT writes as follows: The following are briefly the points to be laid before the Secretary of State for India connected with the Indian Medical Service.

1. The need of putting a stop to military surgeons going into civil employ or duty.
2. To cause all military surgeons now in civil work to return to military duty.
3. To throw the so-called "expert" or "specialist" posts and leading appointments open to competition in India and in England.
4. To instal the unconvincant as the nucleus for the Indian Civil Medical Service, and to fill up all Civil vacancies from the special allocations that will be made to this service.
5. To utilise military surgeons and assistant surgeons with British and Indian troops under a central organisation, which is tantamount to the amalgamation of the Army Medical Staff and Indian Medical Service.

"* This programme must, in our opinion, sooner or later be adopted.

RETIRED PAY APPOINTMENTS.

It is rumoured that Brigade-Surgeon Whipple will obtain a five years' extension at the Duke of York's School. Another rumour, that the medical staff of the Royal Hospital, Chelsea, is in future to be drawn from the active list and posted for five years, is, we think, very unlikely. Such an appointment requires an officer of age and experience, and it would be most undesirable to change him at the end of five years. The comfort and well-being of the old pensioners is the first and chief consideration in the appointment of a medical officer. If, through the operation of age retirement, the hospital should lose the services of Dr. Ligertwood, who has so long and ably filled the post, he will be greatly missed by many of the old men, who are deeply attached to him.

ENTERING THE MEDICAL STAFF.

None—Private income, however desirable, is not absolutely necessary in the Army Medical Service, and no one could possibly be looked down upon because he has not got it. The pay, to commence with, is over £200 a year, and is increased by quinquennial increments. It varies in amount according to where the officer may be quartered abroad, and according as there may be local allowances. He may put down the cost of uniform, outfit, etc., at say £50. Full information can be obtained by application to the Director-General, Army Medical Department, 10, Victoria Street, Westminster, S.W.

WAR OFFICE ORGANISATION.

Our PRICES writes: The attention of the medical profession should be drawn to the proposed War Office reorganisation sketched by the War Minister on the evening so eventful to him. The proposal was to "concentrate direct responsibility to the Minister of officers charged with certain well-defined duties." While the new Commander-in-Chief will be the principal military adviser of the Secretary of State, he, with the "other heads of military departments, will each be directly responsible to the Minister." Such an arrangement, our correspondent points out, ought to bring the head of the medical department into direct contact with the Secretary of State for War, which would prevent him and his department being made the subject of War Office failures. It would surely, for instance, prevent the miserable shuffling and recommitments which took place after the Egyptian campaign of 1882, and saddle the real authors of breakdowns with the responsibility which they are only too ready to evade from afterwards. It is therefore important that in any new scheme of War Office reorganisation the medical profession should insist in Parliament on justice being done to the Army Medical Department.

ASK LEAVE TO MEDICAL OFFICERS.

Our PRICES writes: You have often protested against the injustice of only allowing medical officers half the ordinary time on sick leave; and then placing them on half pay which was not counted as service either towards promotion or retirement. Indeed, how very active during the past fifteen years to get their regular regulation altered, I have the pleasing duty to inform you that those strategic regulations have been done away with. The time has been extended to its normal length, and by Article 100 of the War Warrant one year on half pay now counts towards retirement, and the Warrant of 1891, expiring next month, will further provide for one year on half pay counting towards promotion. No longer delayed justice has at last been done.

"* We are very glad to hear it. It is an acknowledgment by the War Office that the former regulation was unjust.

MEDICO-LEGAL AND MEDICO-ETHICAL.

THE PHARMACY ACTS.

ON June 27th Messrs. Fanning, the well-known surgical instrument makers in Putnam, were prosecuted by the Pharmaceutical Society of London for having kept open shop for the sale of poisons, not being properly qualified to do so under the Act. The case was admitted, but it was pointed out that Dr. Whittaker, one of the proprietors, was a medical man. The magistrate fined the defendants £2 in each of three cases.

A CURIOUS LUNACY CASE.

AN inquiry has just been held at Longford on a charge made by the police against the surgeon, Dr. Mayne, in reference to his behaviour in removing a lunatic patient from the hospital. It appeared that the woman had been admitted for lunacy and confined by her in an attempt to commit suicide by throwing herself from a window. She was brought only insane. Dr. Mayne after a time wanted to have her removed, but Dr. York refused to certify that she was fit for removal. Dr. Mayne applied to the Chief Secretary for instructions, but not receiving a reply, he carried the woman outside the hospital, and deposited her in the street in presence of a policeman. It was then necessary to remove her to the barrack. The Lord Justice indicated an inquiry. Dr. Mayne said he charged the woman as a dangerous lunatic, and that was duly arrested. The governors eventually found that Dr. Mayne acted for the benefit of the other patients in the infirmary.

MEDICAL ETIQUETTE.

A. was acting as locum tenens for a doctor who was away on holiday, and was called to see a girl one night about 6 P.M. A. saw her, and prescribed. At 9 A.M. next day A. got a letter from the father of the girl saying that she had been much worse through the night, and that early in the morning he had fetched another doctor, B., who saw her by himself. The father says he has "no fault to find with A., but one has more confidence in a doctor one knows." The father then adds, "B. is coming to see her again to-day, at 12 o'clock, and would like to have met A., but I think I would like B. to take charge of the case; however, I have no objection to A. coming back again."

"* The above instructive case is governed by the following rule (9) of the Ethical Code, chap. II, sec. 5: "When a practitioner is called in to, or consulted by, a patient who has recently been, or still may be, under the care of another for the same illness, he should on no account interfere in the case, except in an emergency, having provided for which he should request a consultation with the gentleman in previous attendance, and decline further direction of the case except in consultation with him," etc. Under the circumstances related, and in view of B.'s expressed wish, we are clearly of opinion that A. would have acted wisely and in the interest of his principal by meeting him (B.) in consultation. It is scarcely necessary to add that the father's action in the matter was consistently natural, and that of B. apparently in conformity with the above rule.

GLYCOSURIA AND DIABETES.

DR. CAMPBELL D. BLACK, M.D., Professor of Physiology in Anderson's College, Glasgow, writes: Apropos of your remarks on the above subject in the BRITISH MEDICAL JOURNAL of June 29th, will you allow me to give the following experience, which may to some extent explain the discrepancy in the examinations of the gentlemen concerned? The other day I presented to my practical physiology class a specimen of urine which appeared puzzling. The case is that of a man about 60, and there is neither excessive thirst nor pronounced emaciation. When I first examined the urine it certainly contained sugar. The following complications exist: there is prostatic enlargement, with cystitis, and more or less pus in the urine, with glycosuria and uricæmia. On the occasion of my first examination of the urine I removed the ammonium, the phosphates, and the urates, in the usual manner; and I got the various characteristic glucose reactions. On the second examination the albumen alone was removed, and Fehling's solution gave no reaction up to and during the boiling, but as the liquid cooled, a copious greenish-yellow precipitate resulted. The "Fehling" was quite unimpeachable, and there can be no doubt that the result obtained was due to the abnormal presence of phosphate and urates. The urine evolved no carbonic acid in presence of yeast, nor did it give any reaction when mixed in the cold with "Fehling" for over twelve hours. Repeated testings showed that this precipitation depended on the amount of the "Fehling" used. If the quantity used was small, no precipitation took place on cooling. To obtain this, about a quantity equal to that of the urine had to be employed, and then the precipitate was copious. I have again examined the patient's urine to-day, and I feel undoubtedly that it does contain sugar. It gives the usual reaction with "Fehling" and Benedict's test, and the yeast test. The urine is alkaline, and on microscopic examination now shows no phosphate crystals as it formerly did, but on a few pus cells and granular matter in small amount. There can be no doubt that, particularly in aged persons, sugar may occasionally disappear in the urine for days at a time, and thus A. and C. might both have been right.

UNIVERSITIES AND COLLEGES.

UNIVERSITY OF CAMBRIDGE.

APPELHROOKE'S HOSPITAL.—At the quarterly meeting of governors held on July 1st, Dr. E. Carter, of St. John's College, retired from the office of surgeon after twenty-four years' service, and was, on the proposal of Professor Sir G. M. Humphry, unanimously re-elected consulting surgeon to the hospital. Dr. Joseph Grimes, M.A., M.D., F.R.C.S., of King's College, Assisted to the Professor of Surgery and Hunterian Professor at the Royal College of Surgeons, was elected and promoted from the position of Assistant Surgeon to the full surgeon. This appointment left a vacancy for an Assistant Surgeon, and Mr. W. H. Bailey, M.B., M.R.C.S., of King's College, University Lecturer in Medicine, was elected opposition, elected to the vacant office. Mr. A. Parnham, M.B., M.R.C.S., was at the same time appointed House Physician. The final steps were taken for the creation of a new building to accommodate an improved plan, the surgery and professors of the hospital. The cost of the new block will be about £10,000, part of which will be met by means of two recent

and a fine of \$1000 is required for the three years' course in training.

SUMMER SCHOOL OF MEDICINE.—Some twenty practitioners have come into residence for a week's course of lectures and demonstrations in surgery is connected with medicine, and appear to be quite satisfied with the arrangements made for their convenience and instruction.

FIRST EXAMINATION IN MEDICINE, SUMMER, 1886.—The following candidates have passed this examination:

UNIVERSITY OF DUBLIN

At the summer commencement of Trinity Term, held on June 28th, in the Theatre of Trinity College, the following, among other degrees, were conferred by the University Capt in the presence of the Senate:

Licentiate in Medicine, in Chirurgia, et in Arte Obstetricâ.—J. C. Ennis.
Baccalaureus in Medicina, in Chirurgia, et in Arte Obstetricâ.—B. J. Arundel, S. J. M'C. Bradshaw, A. E. Brunsell, E. W. W. Cochrane,
R. Friel (B. Ch. sup. cond.), H. W. Irvine, T. P. G. Kirkpatrick, E. F. L. Macdonald, A. H. McNeill, James Mackay, W. Milne, E. I. Parry Edwards,
I. I. Prichard, J. J. Purser, and S. Sprue.

Doctors in Medicine.—R. J. Arundel, G. H. Blood, S. M. Cox, G. C. Deane, F. W. O'Connell, J. P. C. Kirkpatrick, J. Cunningham, R. H. McCauland, J. S. Morton, A. Moore, G. M. Thompson, G. J. Thompson, A. Vigne, and E. W. Wade.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF
PHYSICIANS AND SURGEONS.

The following gentlemen passed the Second Examination of the Board in the subjects indicated at a meeting of the Examiners on Monday, July 1st:

Paused in Anatomy and Physiology.—H. J. Taylor and W. A. Thompson, *Students of Owens College, Manchester*: H. S. Clogg, of University College, Cardiff; T. W. Byrne and M. R. Maher, of University College, Liverpool; A. W. S. Curtis, O. H. Rogerson, W. H. Galloway, P. E. Middleton, R. Milnthorpe, and E. A. Wraith, of Yorkshire College, Leeds; J. Phillips, E. M. Pearce, and F. Cox, of University College, Bristol; I. B. Richardson, J. A. O'Doud, W. A. Henshaw, J. O. Harvey, and E. C. B. Hall, of Nason College, Birmingham; and E. R. St. J. Caro, of Michigan University, U.S.A.

Passed in Anatomy only.—C. H. Bradbury, of Owens College, Manchester; and S. Welby, of Oxford University and St. Thomas's Hospital.

Passed in Physiology only.—G. W. White, of Firth College, Sheffield; S. B. Reid, of Cambridge University; C. M. Mitchell and F. C. Morgan, of University College, Bristol; and L. H. Lewis, of Guy's Hospital and University College, Cardiff.

Of these patients, 10 were referred in both subjects, 4 in Anatomy only and 6 in Physiology only.

Tuesday, July 2nd.

Practical Anatomy and Physiology.—S. H. Belfrage and C. H. Bidwell, students of University College, London; A. Gentel and C. D. Leydon, of St. Mary's Hospital; J. L. Lewis, of Queen's College, Belfast; P. D. Powell, of St. Thomas's Hospital; R. C. Barlow, of Westminster Hospital; W. E. A. Worrie and E. C. Morland, of St. Bartholomew's Hospital; D. K. L. Nasmith, of Charing Cross Hospital; and J. P. M. of King's College, London.

Passed in Anatomy only.—R. S. Ransome, G. H. Dominy, and A. E. Malaher, of St. Thomas's Hospital; O. T. A. Phillips, of University College, Cardiff; and N. Buendia, of St. Bartholomew's Hospital.

College, Canada; and N. Buchdala, of St. Bartholomew's Hospital.
 Placed in Pharmacology: E. J. Doolin, of King's College, London; T.
 H. Bailey, of King's College, London; and Mr. Cooke, a School of
 Anatomy and Physiology; A. W. Penrose, F. Ashby, and J. L.

Anatomy and Physiology: A. W. Penrose, E. Ashby, and J. L. Payne, of Guy's Hospital; W. Green and W. H. Park, of Charing Cross Hospital; A. J. Pattison, of London Hospital; J. M. Carvill, of London Hospital and Mr. Cooke's School of Anatomy and Physiology; G. Belay, of St. Thomas's Hospital; and F. A. Pitts Tucker, of St. Thomas's Hospital and Mr. Cooke's School of Anatomy and Physiology.

Eleven gentlemen were referred in both subjects, 8 in Anatomy only, and 3 in Physiology only.

Passed in Anatomy and Physiology.—C. G. Watson, A. O. B. Wroughton, and R. Hatfield, students of St. Bartholomew's Hospital; C. M.

Goodbody, E. F. C. Dowling, R. F. Howlett, and A. G. Graham, of St. Thomas's Hospital; T. Leah, D. Bellolis, W. H. R. Liddell, and J. H. Ishikawa, of St. Mary's Hospital; L. D. Saunders, of King's College, London; H. J. M. D. S. Barker and C. Shepherd, of Guy's Hospital; W. St. A. F. Hubbard, of Charing Cross Hospital; H. T. Barrow, of Westminster Hospital; F. M. Morris, H. G. Frankling, and J. A. P. Cullen, of London Hospital; and C. B. Fairbank, of University College, London.

AND

POOR-LAW MEDICAL SERVICES

HEALTH OF ENGLISH TOWNS

18 thirty-three of the largest English towns, including London, 6,166 births and 8,394 deaths were registered during the week ending Saturday, June 24th. The annual rate of mortality in those towns, which had been 15.4 and 18.3 per 1,000 in the two preceding weeks, further rose to 16.7 last week. The rates in the several towns ranged from 9.6 in Brighton, 9.9 in Derby, and 11.5 in Huddersfield to 21.0 in Salford, 22.8 in Gateshead, and 35.7 in Liverpool. In the thirty-two provincial towns the mean death rate was 16.6 per 1,000, and was 0.4 below the rate recorded in London, which was 16.9 per 1,000. The zymotic death rate in the thirty-three towns averaged 2.4 per 1,000; in London the rate was equal to 2.2 per 1,000, while it averaged 1.9 in the thirty-two provincial towns, and was highest in Salford, Liverpool and West Ham. Measles caused a death rate of 1.5 in Newcastle-upon-Tyne, 1.7 in Cardiff, 1.8 in Plymouth, and 2.9 in West Ham; scarlet fever of 1.0 in Burnley; "fever" of 1.0 in Huddersfield; and diarrhoea of 2.3 in Salford and 3.1 in Leicester. The mortality from whooping-cough showed no marked excess in any of the large towns. The 56 deaths from diphtheria in the thirty-three towns included 38 in London, 3 in Liverpool, 2 in West Ham, 2 in Portsmouth, and 2 in Birmingham. One fatal case of small-pox was registered in London, but not one in any of the thirty-two provincial towns. There were 84 small-pox patients under treatment in the Metropolitan Asylums Hospitals and in the Hospital for Small-pox on Saturday last, June 24th, against 24, 18, and 22 at the end of the three preceding weeks; 25 new cases were admitted during the week, against 5, 2, and 8 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital was 1,594, against 1,688, 1,937, and 1,732 at the end of the three preceding weeks; 319 new cases were admitted during the week, against 179, 196, and 251 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

During the week ending Saturday last, June 25th, 1,008 births and 544 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had been 17.1 and 14.6 per 1,000 in the two preceding weeks, declined to 10.2 last week, but was 2.7 per 1,000 above the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 1.2 in Leith to 27.4 in Perth. The zymotic death-rate in these towns averaged 2.7 per 1,000, the highest rates being recorded in Edinburgh and Paisley. The 278 deaths registered in Glasgow included 26 from diarrhoea, 6 from measles, 6 from whooping-cough, and 2 from diphtheria.

EDINBURGH CITY BYRES

A REPORT has been presented to the Corporation of Edinburgh by Messrs. A. R. Young, M.R.C.V.S., and John Gibson on the city byres. By "The Cattle Sheds in Burghs (Scotland) Act, 1886" it is ordained that for every animal kept in a byre there shall be at least 800 cubic feet of space, but the reporters found that out of the 175 byres in the city, containing 2,204 cows, in only 18 cases did the cubic space amount to 800 feet, and in three byres the cubic space was under 300 feet. This alarming overcrowding depended on the following causes:

1. The licence was granted for too many cows.
2. More cows were kept than the licence authorised.
3. Animals were allowed to occupy the space set apart for the gangway.
4. The licence failed to specify the number of cows allowed for each type.

The report recommends that instructions be issued peremptorily insisting that in every byre within the city each cow should have at least 100 cubic feet of air space, which would tend to improve the health of the animals, to ensure a better milk supply, and at the same time lessen the risk of tuberculosis and pleuropneumonia.

ing and ventilation was in many cases very inadequate. In some of the cases the cows were housed in total darkness, while in others the sole means of ventilation was afforded by a defective roof. Very seldom was there any provision for sickness or other suspicious symptoms occurring among the stock in the shape of separate accommodation for affected animals, and this was an almost essential requisite in all well-regulated dairies. There had been a marked improvement during the past year in the cleanliness of the cows, but still there is much room for further improvement.

The reporters think the arrangements for the systematic inspection of byres are defective, and suggest that one veterinary inspector of the city staff and also the dairy inspector should be empowered to devote themselves to this inspection, and that these officials should report quarterly to the Public Health Committee on the various points referred to in the statement.

PERTH AND THE INFECTIOUS DISEASE (NOTIFICATION) ACT

The municipality of the fair city of Perth distinguished itself a couple of months ago by the rejection of a proposal for the adoption of the Infectious Disease (Notification) Act.

ious disease (No. 10,000). Act, which had been brought forward in an extremely reasonable and intelligent manner by the Lord Provost and some other enlightened members of the Town Council. The arguments with which we have been rendered familiar in other reactionary quarters were again trotted out, and the suggestion was even made that medical men would in default of actual cases, invent them. All the cases of infectious disease which occurred in the town were, it was said, already known to the sanitary authority, and the favourable opinion of the medical officer of health was treated with disdain. Needless to say, however, he had already followed hard on the heels of the corporation, although they knew it not. The report of the medical officer for the month of May furnishes an illustration of retribution which it would be difficult to parallel. He had in the course of the month discovered that a certain "close" in the town had been a hotbed of disease since the beginning of the year. A death from typhus had been registered in the case of a woman admitted to the infirmary from this close; and a second case had been admitted from another part of the town. Following up the clue thus afforded, the medical officer ascertained that in the month of January a woman in the close referred to had had an illness, which appears to have been mistaken for typhoid. There went down in succession a daughter, a son, another daughter, and another son. On the first of the cases afterwards recognised as typhus occurred, and on the same landing two young women and a young man were laid prostrate by the disease. Later on another woman in the same close was removed to the infirmary suffering from typhus. At this precise time the members of the corporation were proclaiming that the local authority was fully informed as to the existence of infectious disease in the town. With such an object lesson before them, it may be hoped that the ratepayers will take matters into their own hands, and compel their representatives upon the Town Council to take the necessary steps to prevent their town being threatened by disease, and to remove the reproach of being a plague spot from the town.

ROTHERHAM WATER SUPPLY

Dr. Robinson, the Medical Officer of Health of the Borough of Rotherham, has some significant remarks to make in his annual report for 1894 concerning the water supply of the town in relation to disease prevalence. He states that the death-rate was last year the lowest on record since the borough was incorporated over twenty years ago. This happy state of affairs he attributes to the closure of the Wellgate spring in the centre of the town, the spring to which Dr. Theodore Thomson, when reporting on epidemic typhoid fever in Rotherham a year or two back, drew such just and attention as endangering the water supply of the district, as it was in the midst of a populous town, and drawing its contents as it did from a subsoil which had been long subject to excremental fouling. Indeed, it will be remembered that Dr. Klein had to condemn the well on account of the evidence of excremental pollution of its water. The town council were warned as to the state of the well, and now we are informed that it has not been in use since 1893, with the result that the deaths from diarrhoea, which had in the eight years 1885-92 averaged 37 deaths annually, and which were as high as 78 in 1893, fell last year to 7 only. "These figures," says Dr. Robinson, "speak for themselves, and in conjunction with the results of chemical analyses, prove that the water should be permanently cut off as a source of domestic supply."

THE PRINTING OF HEALTH OFFICERS' REPORTS.

The matter of the printing of the annual reports of medical officers of health is one that seems to come up with yearly regularity in one or more counties. It now arises in Essex, and it appears to us to be a pity that it should not have been settled in the past in favour of the compulsory printing of such documents. The value of a report on a district is greatly enhanced when it has been placed in permanent form, and the certainty that the report would be so placed in type would be an incentive to those officers who know that, as matters stand, their production will probably be "put" before their council, and in this way see the end of their career. We venture to think that it will be a distinct advance in sanitary administration when it is made a requirement that all annual reports of medical officers be printed. The amount of clerical work now demanded of these officers before statutory requests are met is, in itself, a bad and not an effective remedy in localities where reports are themselves worthy of the printer's charges.

COMBINED DRAINAGE SEWERS AND DYPHTHERIA

A report has been presented by Dr. Alexander to the Poplar District Board, in connection with the difficulties now being experienced by sanitary authorities in dealing with the redeigning of groups of houses drained by a combined system. Under the definition of the Metropolitan Management Act the word drain includes "any drain for draining a group or block of houses by a combined operation laid or constructed before the first day of January, 1891, in accordance to the order or direction, or with the sanction or approval, of the Metropolitan Council, or of any sewer or sewerage authority." Dr. Alexander points out that a considerable amount of his time has been taken up in dealing with the problem, connected with the Metropolitan Council, of sewerage, with a view to the settling whether particular drains remained the property of the local authority. In the case of Poplar such a search would be a matter of some difficulty, as the system is a combined one, only four of which "have any kind of label." Dr. Alexander's report has been presented with a view to the removal of the Metropolitan Council's jurisdiction in connection with the combined operation for bringing about an improvement of the law relating to sewer or drain.

Dr. Alexander has also written a paper in which he deals with the subject of sewer and diphtheria. He discusses the improved arrangements which have recently been made by means of a new sewer for carrying off the sewage of the line of Poplar, and the importance of the sewerage and the sewerage, and he states that "it has been a very interesting to note the local public health authorities in the Poplar and District parishes for the past few weeks, which have been the case, and which has been the case." The paragraph which follows in the report does not, however, deal in any detail with the points of the case, but the Medical Officer's attention has been directed.

LUNACY ORDERS

"CONSENT" statement is not clear. The guardians cannot pay the medical officer of a workhouse for a certificate in support of an application for an order by a justice for detention of a lunatic in a workhouse. As to whether or not they are bound to pay such medical officer for a certificate in support of an application for an order under which a lunatic in such workhouse may be or is removed to an institution for lunatics, everything turns upon the agreement or understanding the medical officer has with the guardians with regard to the duties he is to perform for his fixed salary. If by it he is to perform all the duties and work that fall in the way of a workhouse medical officer of lunatics for a fixed salary, he has, of course, no claim for extra fees, but if there is not such understanding, there is nothing illegal in the guardians paying for such certificate, if and as ordered by the justice who gives the "order" for the lunatic's reception into an asylum.

TYPHUS FEVER AT BURY.

A RECENT report by Dr. Monckton Copeman on an outbreak of "fever" at Bury, in Lancashire, is of interest. After 2 and 3 cases respectively of "continued" fever had been notified in the first two quarters of 1894, the notified cases suddenly rose in the next quarter to 25, with 5 deaths, 8 typhus cases being notified in the same three months, with 7 deaths, and also 15 enteric cases, of which 11 proved fatal. Dr. Copeman, after visiting the hospital and conferring with the health officer, Mr. Ashworth, came to the conclusion that the majority of the continued cases were in reality typhus, and that enteric fever had also been diagnosed when the malady was in fact typhus. Fortunately the health officer was at an early stage alive to the gravity of the situation, and by prompt measures stayed what would otherwise probably have proved a wide dissemination. The typhus was spread largely by personal intercourse, and interesting charts and a genealogical tree of attacks are given.

THE SPREAD OF CONTAGION IN SCHOOLS.

THE Board of Health of the city of Boston, U.S.A., has instituted a system of school inspections with a view to preventing the dissemination of infectious disease. The plan adopted was as follows: A list of the children whom it was considered desirable the doctors should see was prepared by each teacher and sent to the head teacher by 6 o'clock every morning. Examination was made of these children by the doctor on his arrival, minimum of disturbance of the ordinary school routine being as far as possible secured.

DISPENSARY DOCTORS AND VACCINATION FEES.

THE Local Government Board in Ireland has written a reply to certain questions submitted to it by the Rathdown Board of Guardians. It declares that a medical officer is entitled to be paid for each case of successful vaccination performed by him, whether the person vaccinated by him is or is not resident within his sub-district. A dispensary medical officer is not bound to perform vaccination except at the dispensary and the vaccination stations within his district or sub-district, and the guardians should not allow fees for persons vaccinated elsewhere. A gentleman employed as a temporary substitute for a dispensary medical officer is entitled to fees for vaccinations performed and certified by him as acting public vaccinator. It is not usual for medical officers to charge Boards of Guardians for the vaccination of persons in respect of whom they had received remuneration for their professional services.

WATERBORNE DIARRHŒA.

THE Medical Officer of Health for Rotherham (Dr. Alfred Robinson), in his annual report just issued, gives the death-rate as 18.61 per 1,000, against 18.70 in the previous year. These figures are the lowest on record since the borough was incorporated twenty years ago, but the important matter about the report is that the diminished death-rate is attributed to the abandonment of the Wellgate water as a source of domestic supply. During 1894 this water had not been used, and the very startling fact was chronicled that the deaths due to diarrhoea were only 7, whilst when this water supply was used in the previous year the deaths numbered 78.

THE VESTRY OF ST. GEORGE SOUTHWARK AND ITS MEDICAL OFFICER OF HEALTH.

IN THE BRITISH MEDICAL JOURNAL of April 18th reference was made to an unusual proposal which was put forward by members of the vestry of St. George Southwark. The suggestion was made that the medical officer of health should pay what a member of the vestry called "surprise visits" to his employees, with a view to detecting any "sneaking" The medical officer of health stated that such visits could only be made by him in consultation with the medical men in attendance upon the patient. To this it was objected, however, that any request for the nature of ordinary etiquette would defeat the object in view. The proposal of the surprise visit scheme persisted in their controversy, and the medical officer was informed that he was expected to carry the system into execution. At the vestry meeting on May 2nd Dr. Waide again pointed out that the members of the profession were opposed to a second medical man visiting a case without the sanction or knowledge of the first. It was thereupon determined to refer the question to the Local Government Board for decision. It may be supposed that the Local Government will not hold that the payment of visits of the kind indicated forms part and parcel of the duties of a medical officer of health.

WEST-H BOARD OF GUARDIANS.

WE are pleased to see that at a recent meeting of this Board the Hon. J. Thomas raised the question as to the provision for the guardians of all extensive medical and surgical appliances, pointing out that it was unreasonable to expect their medical officers to supply such things out of

Account to the Local Government Board on an outbreak of "fever" at Bury, Lancashire, by Dr. Monckton Copeman, East Harding Street, E.C. 4, p. 10.

their salaries. It appears from the discussion which ensued that when applications had been previously made to the Board to provide these salaries the requests had been refused. The proposal of Mr. James was, however, unanimously adopted. This is as it should be and we hope to see many other Boards of Sanitation take this correct view of their duties, and follow the excellent decision of the Woburn Board.

DIPHTHERIA AND SCHOOL ATTENDANCE.

The casual relation of school life to diphtheria spread is shown unmistakably in a recent outbreak in diphtheria at Putnam, in the Tennessee River district, by Dr. M. M. Thompson. The disease seems to have started early in July, 1893, in what were looked upon as mild throat illnesses in scholars at the national school, and these cases were unattended by any medical man. The graver malady soon developed, and by the end of the month, some 100 cases had dropped out, some of them of a malignant character, and by the end of the year there had occurred 100 cases in 100 houses with 20 deaths, a mortality rate of 20 per cent of known cases. The schools were repeatedly closed and reopened, with the result of further cases springing up both during periods of closure and also, and especially immediately after the reopening of the schools. Care was taken by the health officer to prevent the attendance of suspicious throat cases, but the disease went on until October, 1894, when 140 cases had been heard of in 60 households, and of these not one was among the large number of children of the well-to-do residents in the place. Dr. Thompson is upon school mingling of children and other personal relations as chiefly accounting for the spread of the disease. He also regards the absence of proper hospital accommodation when the epidemic commenced as responsible for the dimensions of the prevalence, although the school and all they could by way of extemporised means of isolation, nursing, and the like. We find the isolation of 60 patients and another 60 cases and the death of 20. Of 40 Putnam patients treated in hospital, 2 per cent died, whilst of 40 home-treated patients 24 per cent died. This fact indicates the most malignant cases were those removed for isolation, and they saved, it may be, many more attacks from entering the homes from whence they were removed.

HALIFAX SMALL-POX ISOLATION ARRANGEMENTS.

We much regret to see that the Town Council of the borough of Halifax have practically decided to abandon their long thought of scheme for the location of small-pox patients belonging to their town. Many months since a site of some 60 acres in extent was purchased for the ostensible purpose of thereon erecting a hospital for the treatment of small-pox cases, the site being so placed that, so far as we can learn, there would have been no objection to the use of the ground for the purpose in question. And now the old story comes up again of the immediate danger to the public health which led to the purchase having been made, and the whole scheme upon that danger being more within hopeful distance of being carried out the purpose strings are suddenly tightened because, forsooth, "no further outbreak may occur for the next fifteen or twenty years." Quite true, so also a fresh outbreak may spring up in the present year. But, no matter when—in inevitable as it may seem in the face of the experience of Halifax in 1892-93—the further proposal is to leave the question of small-pox hospital provision over "until the disease appears again." And then temporary means are to be adopted. We can only hope that the scheme already thought out will not be allowed to drop in such a manner.

SOME RURAL DIFFICULTIES.

CYNDO D.P.H. asks: 1. What work will give him the best information as regards the best mode of conveying a water supply from, say, a spring by gravitation to a house, leaving a supply at its source for a cottage or almshouse.

2. Is it necessary to give forty-eight hours' notice to the rector if it is desirable to bury a parishioner in his churchyard not in accordance with the rites of the Established Church, granted the body in any way because a paralytic or injurious to health, is there any means by which the body could be buried in less than forty-eight hours? I do not refer to a death from infectious disease. There is no public mortuary in the parish.

3. What is considered the best disinfecting agent for a room say from catarrhal complaints? I have been told that a mixture of solutions of common salt and acetate of lead are very effectual, but can find no reference to such a mixture or mode of preparation for such object.

"* 1. On this point we would recommend our correspondent to consult an engineer with opportunities for acquainting himself with the conditions to be dealt with.

2. There is a clause in the Infectious Diseases Prevention Act, 1890 (if that is in force in the district) under which a magistrate upon application of a medical officer of health can deal with cases in which a corpse is retained in a building so as to endanger the health of the inhabitants.

3. A mixture of common salt and acetate of lead would not, so far as we can ascertain, be effectual. Perhaps carbolic acid or one of the essential oils might be employed with a view to masking the odour.

THE SEIZURE OF MEAT.

J. H.—Either the medical officer of health, or the inspector of nuisances acting alone, has the right to seize if the article appears to him to be unsound or unwholesome or unfit for the food of man; and to carry it before a magistrate, with whom alone it rests to condemn the article and order it to be destroyed. In the case in point the action of the inspector must be regarded as a seizure, whether so intended or not, and as a seizure seizure of meat which was not fit for food, since the superior officer, the medical officer of health, negatived the in-

spector's opinion as to unfitness. It seems that the magistrate, though present, was not officially called upon, and that the carcass was returned to the owner and accepted by him. Under such circumstances the corporation would properly be liable for any damage that could be shown to result from their officer's mistake in seizing presumptively unwholesome meat.

NOTIFICATION CERTIFICATES.

A. B. C. writes: What is the correct course to adopt as medical officer of health or where a local practitioner constantly sends notification stamps upon through the post, upon each of which I am charged 2d. (1) where a disease is notified and, upon visiting the house for inspection immediately upon receipt of notification, I find that no such disease exists.

"* (a) The Local Government Board have held that deduction may be made from the fees to notifying practitioners under the Infectious Diseases (Notification) Act of the amount charged by the postal authorities in respect of certificates posted unstamped. But in the case of Chisholm v. Radcliffe Local Board, Judge Jones decided to the contrary. In any case, we assume that a medical officer of health would in the first instance reclaim from his council all amounts so paid by him to the postal authorities. (b) It is held that that difference of diagnosis does not of itself warrant rejection of a certificate of the medical attendant on a case, and it is not one of the duties of the health officer to verify notified diagnosis in general. But where proof exists of mala fides on the part of the certifier, the facts should be laid before the council; and where there seems to be ground for such a grave suspicion, it is proper for the medical officer of health to communicate with the notifier and to make a thorough investigation.

LITERARY NOTES.

One of the most recent additions to periodical medical literature in Germany is the *Archiv für Verdauungskrankheiten*, founded and edited by Dr. J. Boas. The new journal takes all that appertains to disease of the digestive apparatus, disorders of metabolism, and dietetics for its province.

The *Journal des Connaissances Médicales* has unearthed the following anecdote concerning Claude Bernard. After his paper on the functions of the pancreas was presented to the Académie de Médecine (in 1849), Magendie got him the decoration of the Legion of Honour without his knowledge. By a curious misprint the *Journal Officiel* announced that Claude Bernard, of Villefranche, had been named a Knight of the Legion of Honour for his valuable research on the muscular (instead of "medical") properties of the pancreas. The slip was corrected in the journal on the following day, but it seems to have become a kind of obsession in Bernard's mind, and he was always in some trepidation when lecturing on the pancreas lest he should refer to its "musical" properties.

Professor Edmond Souchon, of Tulane University, New Orleans, has republished some interesting "Reminiscences of Dr. S. J. Marion Sims," which appeared not long ago in the *New York Medical Record*. Dr. Souchon was in Paris studying medicine when he first met Sims, who had gone to the French capital to demonstrate his new method of operating for vesico-vaginal fistula. Dr. Souchon introduced Sims to Velpeau, and made himself useful as an interpreter and as an assistant at the operations which the American surgeon performed before his brethren of the Paris faculty. His triumph was complete, though in two of the earliest operations the patient narrowly escaped dying under chloroform, which was given against Sims's wish. Sims repaid the services rendered him by Dr. Souchon by helping him in the most generous manner at a time of need, and other instances of his kindness of heart and liberality of hand are given. Altogether the memoir, even allowing for the partiality natural under the circumstances, leaves a very pleasant impression of Marion Sims. Incidentally Dr. Souchon, who, by the way, is a Professor of Anatomy and Clinical Surgery, enriches the English language with a new word, which in the present set of the shifting currents of abdominal surgery may be found useful, though it can hardly be considered ornamental. After mentioning that Sims was at one time subject to attacks of pain and swelling in the right iliac region, which caused him some concern, he goes on to say: "Surely if it had been some years later he would have been appendicitized." He piously adds: "But, thank God, he got well without the knife."

In the *Bulletin of the Johns Hopkins Hospital* Dr. Hunter Robb, Professor of Gynecology in the Western Reserve University, Cleveland, Ohio, gives an account of the writings

* Report to the Local Government Board on an outbreak of diphtheria at Putnam, N. H. Messrs. Eyre and Spottiswoode, East Harding Street, E.C. Price 1s.

of François Mauriceau, an old French obstetrician of credit and renown in his day. Mauriceau, whose professional titles are somewhat too literally translated by Professor Hunter Robb as "ancient provost and guard of the company of sworn Master Surgeons of the City of Paris," was born in 1637, and died in 1702. He was the author of a work on midwifery, which was the accepted textbook on the subject in France in the seventeenth century and the early part of the eighteenth, and which was translated into English by "one Hugh Chamberlen." Dr. Robb gives an excellent analysis of Mauriceau's teaching, and sums him up as an honest, upright man, who never allowed his common sense to be obscured by the various superstitions which prevailed in his time. Mauriceau lived in an age when the midwife played a more leading part in the drama of the lying-in room than she does now, and the following passage is, therefore, not without interest:

Many midwives, for fear of displaying ignorance, will not send for a surgeon sufficiently soon, and promote the poor women against them, calling them butchers and executioners.

In the *New Zealand Medical Journal* for April, Dr. Daniel Colquhoun sketches the career of Dr. James Currie, of Liverpool, who was, as he justly says, "one of the fathers of modern medicine," though his name no longer *volitat per ora virorum*. Currie was born in 1756, and took his degree at Glasgow in 1780. He practised at Liverpool with considerable success, was elected a Fellow of the Royal Society, and was on terms of friendship with Erasmus Darwin, the author of the *Lives of the Plants* and grandfather of Charles Darwin, and many of the leading literary and scientific men of his day. He died in 1805. His name is known in literature by his *Life of Robert Burns*, and he was also the author of pamphlets on matters of public interest, such as the slave trade (which he wished to see abolished) and the relations of England with France. In medicine his best claims to be remembered are that he was the first physician in Great Britain who used the clinical thermometer systematically and was guided by its teaching. He was also an early apostle of hydrotherapy, and his *Medical Reports on the Effects of Water, Cold and Warm, as a Remedy in Fever and Other Diseases, whether applied to the Surface of the Body or Used Internally*, the first edition of which was published in 1787, show that he was a pioneer in a method of treatment which only in recent years has won for itself full *droit de cité* in scientific therapeutics. Currie's attention seems first to have been called to the value of cold water in fever by Dr. William Wright, who had practised in Jamaica, and who published a report on the subject in the *London Medical Journal* in 1786. Among numerous cases of "fever" (including typhus, typhoid, scarlet fever, small-pox, measles, and influenza) successfully treated by "the affusion of cold water," Currie relates a desperate case of tetanus which he cured by having the patient (a soldier) "thrown headlong" into the public salt water baths of Liverpool, then of the temperature of 35° F. The effect was immediate. The process was repeated daily for a fortnight, and "in less than a month we had the satisfaction of seeing our patient under arms, able for the service of his country." It is sometimes said that as a race we are falling into the sere and yellow leaf, and that we are not as our fathers were; and indeed one cannot help feeling that they must have been men of truly heroic mould to live through the treatment which they often underwent at the hands of their doctors.

MEDICAL NEWS.

ST. THOMAS'S HOSPITAL.—The Corporation of the City of London has granted a donation of 200 guineas to the special fund for the closed wards of this hospital.

A MEMORIAL tablet of the late Dr. Danielssen, designed by Herr Max Klein, of Berlin, has been placed on the front of the Lungegaards-Hospital at Bergen.

PRESENTATION.—Dr. Arthur Parkiss, of Wolston, Warwickshire, has been presented with a pair of candlesticks by the pupils of his ambulance class, all of whom passed the examination.

SUCCESSFUL VACCINATION.—Dr. T. Davies, Public Vaccinator for the Suburban District of the Whittlesey Union, has been awarded for the second time in succession the full amount of Government grant for efficient vaccination.

The fifty-fourth annual meeting of the Medical-Psychological Association of Great Britain and Ireland will be held on Thursday, July 25th, and the two following days at the rooms of the Association, 11, Chandos Street, Cavendish Square, under the presidency of Dr. David Nicolson.

The following medical practitioners have been recently placed on the Commission of Peace: For the County of Lancaster, Dr. James John Gorham; for the Borough of Preston, Dr. Joshua Archer Bowen, and Dr. John Louis, ex-President of the Preston Medico-Ethical Society.

SURGEON-MAJOR RONALD ROSS, Madras Medical Service, has obtained the Parkes Memorial Prize for 1894 for an essay on "Malarial Fevers: their Causation and Prevention." This prize is given triennially, and consists of a gold medal and 75 guineas.

THE war dogs belonging to the German Army, which were shown at the Sporting Exhibition at Dresden, acquitted themselves, it is stated, as successfully in Red Cross duties as in conveying ammunition. The trials consisted in testing the power of dogs in seeking the wounded on the field of battle.

AN "At Home," very largely attended, was given last week at University College, London, by the President (Sir John Erichsen) and the Council. In addition to the attractions afforded by a concert in the Botanical Theatre, and the band of the Royal Engineers, which played in the portico, Professor Ramsay gratified the scientific curiosity of many guests by demonstrating the spectra of argon and helium.

ULSTER MEDICAL SOCIETY.—The annual meeting was held on June 27th. The report showed that the past year had been one of great prosperity, and that the membership had been considerably augmented. The following were elected officers for the ensuing year: *President*, Professor Sinclair, F.R.C.S.; *Vice-Presidents*, Dr. Bingham and Dr. Mackenzie; *Council*, Dr. Lindsay, Dr. Dempsey, Dr. Calwell, Dr. McCaw, Dr. McDonnell, and Dr. Bigger; *Honorary Treasurer*, Dr. Kevin; *Honorary Secretary*, Dr. McKisach; *Honorary Librarian*, Dr. Cecil Shaw; *Pathological Secretaries*, Dr. Lorrain Smith and Dr. Lyness.

GUY'S HOSPITAL.—The prizes were distributed to the successful students at Guy's Hospital by the Master of the Salters' Company on July 3rd. The Treasurer's gold medals for clinical medicine and clinical surgery were presented to Mr. F. J. Steward; the Gurney Hoare Clinical prize to Mr. A. H. Leete; and the Beane prize for pathology to Mr. F. J. Steward. Mr. Lushington, on behalf of the governors, and Dr. Pye-Smith, on behalf of the Medical School, thanked the Master of the Salters' Company for his presence and for the undertaking which the Company had given to contribute £250 a year to the special fund for making up the deficit caused in the funds of the hospital by the agricultural depression.

On June 29th a new Masonic Lodge for the London district, called the Bahere Lodge, and numbered 2,546 on the roll of the Grand Lodge of England, was consecrated by the Earl of Lathom, G.C.B., in the large hall of St. Bartholomew's Hospital, in the presence of some 300 brethren, a very large proportion of whom were present or past Grand Officers. The Lodge has been founded for the convenience of members of the medical profession on the medical staff of the hospital. The Prince of Wales was unanimously elected the first honorary member of the Lodge.

PADDINGTON GREEN CHILDREN'S HOSPITAL.—The buildings of Teck opened on July 1st the new buildings of the Children's Hospital on Paddington Green. The new structure has cost nearly £11,000, whilst the furnishing and other expenses came to some £2,000 or £3,000 more. It will accommodate forty-eight in-patients. Mr. Hanbury, the Treasurer, stated that through the generosity of certain friends of the hospital the new building would be opened free of debt.

GIRLS' SCHOLARSHIP AT ST. ANNE'S.—The Council of the Royal Medical Benevolent College give notice that they will shortly elect to a scholarship at the School of St. Anne's Society, open to the orphan daughter of a medical man. Candidates must be between the ages of 7 and 12, and the father must have been in independent practice in England or Wales for five years. The scholarship provides free education and maintenance. Further particulars will be found in our advertising columns, or can be obtained from the Secretary of the Royal Medical Benevolent College, 37, Soho Square, W.

We are asked to state that the Æsculapius Lodge of Freemasons will give a smoking concert on Thursday, August 1st, at 9.30 p.m., at the Portman Rooms, Baker Street, in honour of provincial and foreign Freemasons, who may attend the annual meeting of the British Medical Association. Foreign, American, and Colonial Masons are specially invited. Masonic clothing will not be worn, and those who desire to attend should communicate with Dr. T. Dutton, 7, Portland Place, London, W., stating the name and number of the lodge to which they belong.

A **MEETING** was held on June 27th at the house of Dr. Herman Weber in support of the Davos Invalids' Home, which was founded eleven years ago and has since been maintained by the munificence of three English ladies whose names are well-known to those who have visited Davos. The unavoidable retirement, owing to ill health, of Mrs. Lord, who has managed the Home with much success and ability, has rendered necessary an appeal to the public generosity in order especially to obtain funds for the purchase of the freehold. For this purpose, and also to provide for the management of the Home in future, the following Committee was appointed: The Bishop of Marlborough, the Hon. Evelyn Ashley, Dr. Harford-Battersby, the Rev. R. R. Resker, Dr. Herman Weber, Dr. Symes Thompson, Dr. C. T. Williams, Dr. William Ewart, and Mr. Arthur Herbert. The help, either direct or indirect, of members of the medical profession, than whom none can better realise the importance of keeping the Home open, is invited by the Committee. The Home is designed to meet the needs of those whose limited resources would not otherwise permit them to take advantage of the health-restoring qualities of the higher Alps.

WILLS AND BEQUESTS.—The late Mr. John Proctor, of Highbury, who died on April 24th, has bequeathed £200 each to Gay's Hospital, the London Hospital, the London Fever Hospital (Liverpool Road), the Charing Cross Hospital, and King's College Hospital; £100 each to the Royal Hospital for Diseases of the Chest (City Road), the Poplar Hospital, the London Temperance Hospital, the North London Consumption Hospital, the Royal Free Hospital (Gray's Inn Road), the Cancer Hospital (Fulham), the Royal National Hospital for Consumption (Ventnor), the City of London Hospital for Diseases of the Chest (Victoria Park), the London Lock Hospital (Westbourne Grove), University College Hospital, the Royal London Ophthalmic Hospital, and the Zenana Bible and Medical Mission (Adelphi); and £50 each to the Metropolitan Hospital, the Middlesex Hospital (for the use of the cancer wards or patients), the Royal Hospital for Children and Women (Waterloo Road), St. John's Hospital for Diseases of the Skin (Leicester Square), the Evangelical Protestant Deaconess's Institution and Training Hospital (Tottenham), and the Hospital for Diseases of the Throat (Golden Square).

MEDICAL VACANCIES.

The following vacancies are announced:

- BIRMINGHAM GENERAL DISPENSARY.**—Resident Surgeon; doubly qualified. Salary, £200 per annum, with an allowance of £20 per annum for club hire, furnished rooms, fire, lights, and attendance. Applications to Alex. Forrest, Secretary, by July 15th.
- BLANDFORD INFIRMARY AND DISPENSARY.**—Honorary Physician. Applications to the Secretary by July 22nd.
- BRITISH INSTITUTE OF PREVENTIVE MEDICINE.**—Assistant Bacteriologist in the Anatomical Department. Salary, £150 a year. Applications to the Director by July 22nd.
- CANCER HOSPITAL (FREE).** Fulham Road, S.W.—House-Surgeon; Appointment for six months. Salary at the rate of £50 per annum, with board and residence. Applications to the Secretary by July 15th.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST. Victoria Park, E.—Resident Medical Officer, doubly qualified. Salary, £100 per annum with board, etc. Applications to the Secretary by July 15th.

CONVENTRY AND WARWICKSHIRE HOSPITAL.—Resident Assistant House-Surgeon. Appointment for six months. Salary, £15, board, maintenance of heat, washes, and spirits, residence, washing, and attendance. Applications to the Secretary by July 30th.

DENTAL HOSPITAL OF LONDON. Leicester Square, W.C.—Two Assistant Dental Surgeons. Applications to J. Francis Pink, Secretary, by July 5th.

FLINTSHIRE DISPENSARY.—Resident House-Surgeon. Salary, £120 a year, with furnished house, rent and taxes free, also coal, light, water, and cleaning, or in lieu thereof the sum of £20 per annum. A knowledge of Welsh desirable. Applications to Thos. Thomas, Secretary, Board Room, Bagillt Street, Holywell, N. Wales, by July 17th.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST. Brompton.—Resident Assistant Physician. Applications to the Secretary by July 15th.

HUDDESFIELD INFIRMARY.—Junior House Surgeon. Salary, £50 per annum, with board, lodging, and washing. Applications to the Secretary by July 15th.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End.—Senior Demonstrator of Anatomy. Salary payable by a percentage of fees. Applications to Munro Scott, Warden, by July 5th.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End.—Senior and Junior Demonstrators of Physiology. Salary for the senior post, £150 a year and a proportion of the fees paid for classes, and for the junior post £50 a year. Applications to Munro Scott, Warden, by July 5th.

NEWPORT AND MONMOUTHSHIRE INFIRMARY. Newport, Mon.—House-Surgeon, doubly qualified. Salary, £100 per annum, with board and residence. (No stimulants provided.) Applications to the Secretary by July 15th.

METROPOLITAN ASYLUMS BOARD.—Assistant Medical Officer for the North-Western Hospital for Fever Patients, unmarried, doubly qualified, and not more than 35 years of age. Salary, £200 per annum during the first year, £150 during the second, and £200 during the third and subsequent years, with board, lodging, attendance, and washing. Applications on forms provided, to be sent to the Offices of the Board, Norfolk House, Norfolk Street, Strand, W.C., by July 11th.

MIDDLESEX HOSPITAL, W.—Assistant Physician, must be F. or M.R.C.P. Lond. Applications to F. Clare Melhado, Secretary-Superintendent, by July 5th.

NATIONAL SANATORIUM FOR CONSUMPTION AND DISEASES OF THE CHEST. Bournemouth.—Resident Medical Officer. Salary, £200 per annum, with board, lodging, and washing. Applications to the Secretary by July 25th.

QUEEN'S JUBILEE HOSPITAL, Earl's Court.—Surgeon. Applications to the Secretary by July 14th.

ROYAL BERKS HOSPITAL, Reading.—Third or Assistant Medical Officer. Board, lodging, and washing, provided, but no salary. Appointment for six months. Applications to the Secretary by July 15th.

ROYAL VICTORIA HOSPITAL, Bournemouth.—House-Surgeon and Secretary. Salary, £100 per annum, with board. Appointment for two years. Applications to the Chairman of the Committee by July 17th.

SHEFFIELD GENERAL INFIRMARY.—House-Surgeon and Senior Assistant House-Surgeon, doubly qualified. Salary for the former, £120 per annum, with a prospective advance of £20 per year for the second and third years; and for the latter £80 per annum, with board, lodging, and washing. Applications to the Medical Staff of the Sheffield General Infirmary, to the care of the Secretary, by July 15th. The election will take place on July 25th.

SUFFOLK GENERAL HOSPITAL, Bury St. Edmunds.—House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications to Henry Bonner, Secretary, by July 15th.

UNIVERSITY OF GLASGOW.—Two Examiners for Degrees in Medicine to examine in Chemistry and Materia Medica respectively. Applications to Alan E. Clapperton, Secretary of the Glasgow University Court, 91, West Regent Street, Glasgow, by July 25th.

MEDICAL APPOINTMENTS.

- ADAMS, Dr.**, reappointed Medical Officer of Health to the Long Ashton Rural District Council.
- ADAMS, P. E.**, M.R.C.S. Eng., L.R.C.P. Lond., appointed Junior House Physician to the North-Eastern Hospital for Children, Hackney Road.
- BRASLEY, J. G.**, L.R.C.P. Edin., L.F.S. Glasg., reappointed Medical Officer of Health to the Rowley Regis District Council.
- BOND, W. A.**, M.A., M.D., B.C. Cantab., D.P.H. Cantab., M.R.C.P. Lond., M.O.H. for the St. Olave District Board, Southwark, appointed M.O.H. to the Holborn District Board.
- BRODIE, W. B.**, M.B., C.M. Glasg., appointed Assistant House-Surgeon and Dispenser at the Worcester Infirmary.
- CARVER, E. M.A., M.D.**, appointed Consulting Surgeon to Addenbrooke's Hospital, Cambridge, on retirement from the surgery.
- COCROFT, M.**, M.D. St. And., M.R.C.S., reappointed Medical Officer for the Masham District of the Leyburn Union.
- DAVIES, Alfred O.**, L.R.C.P., L.R.C.S. Edin., appointed Medical Officer of Health for the Machynlleth Union District.
- DOVER, Edward H.**, M.A., M.B., B.C., M.R.C.S., L.R.C.P., appointed Assistant Surgeon to Addenbrooke's Hospital, Cambridge.

FRANKING, Robert, M.D.R.U.I., reappointed Medical Officer of Health to the Camberwell District Council.

FAUCHET, A. M.B., appointed Medical Officer for the No. 2 District of the St. George's Hanover Square Union.

FORBES, Wm., B.A.Camb., M.B., D.P.H., appointed Medical Officer of Health to the Shipley District Council, *vice* J. J. Rutherford, M.D. St. Asaph.

GARRATT, Joseph, M.A., M.D., F.R.C.S., appointed Surgeon to Addenbrooke's Hospital, Cambridge, *vice* H. Carver, M.A., M.D., retired.

HARRIS, J. P., M.B., C.M. Edin., M.R.C.S., appointed Medical Officer of Health to the Fourth Rural District Council.

HOWES, A. M.B., C.M. Glasg., appointed Medical Officer for the Alberbury District of the Atcham Union.

HUNTER, Frederick, M.D. Durh., appointed Medical Officer for the Stockton District and Workhouse of the Stockton Union.

JONES, Henry T., I.R.C.P., M.R.C.S., appointed Medical Officer of Health to the Donchess Rural District Council.

KELLY, Charles, M.D. Lond., M.R.C.S., reappointed Medical Officer of Health to the East Preston Rural Council.

MAIR, William, M.B., C.M. Glasg., appointed Medical Officer and Public Vaccinator to the Parish of Crumond, Midlothian, *vice* James Macartney, L.R.C.P.S., resigned.

MILLY, H. N., I.R.C.P., L.R.C.S. Edin., appointed Medical Officer for the second District of the Winslow Union, *vice* W. H. Walter, M.D. Brux., resigned.

PROBERT, Mr. Geo., appointed Medical Officer and Public Vaccinator for the North District of the Hexham Union, *vice* Robert Bradshaw, L.A.H. Dub., L.M., resigned.

PRIDEMAN, Joseph, B.A. Lond., M.D. Edin., appointed Medical Officer of Health for Lambeth, *vice* W. Verdon, M.D. Brux., resigned.

QUARRY, M. H., M.B.R.U.I., B.Ch., appointed Medical Officer of the Lambeth Workhouse and Workhouse.

SMITH, Thomas, M.R.C.S. Eng., I.R.C.P. Lond., appointed Medical Officer and Public Vaccinator for the Bramford Spoke District of the St. Thomas's Union, *vice* A. A. Mackintosh, M.B., C.M., resigned.

SOMMERSET, Edward, I.R.C.P. Lond., M.R.C.S. Eng., appointed Medical Officer of Health for the Oundle Union District, *vice* G. W. B. Calcott, M.R.C.S. Eng., L.S.A., resigned.

STODART, W. H. B., M.B., B.S., appointed senior House Physician at the National Hospital for the Paralyzed, and Epileptic, Queen Square, London.

TANNER, George, M.B. Camb., D.P.H., L.R.C.P. Lond., appointed Medical Officer of Health for the Cape Colony.

VALLANCE, Mr., appointed Assistant Medical Officer to the Chelsea Union.

YOUNG, Ralph, B.A. Durh., M.D., M.R.C.S. Eng., appointed Medical Officer of Health for the Hoxton Urban District, *vice* James Gardner, M.B., C.M. Glasg., resigned.

DIARY FOR NEXT WEEK.

TUESDAY.

THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 3 P.M.
Lecture at 4.

WEDNESDAY.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C., 3 P.M.—Lecture by Dr. Beever.

THURSDAY.

BRITISH GYNECOLOGICAL SOCIETY, 8.30 P.M.—Specimens: Dr. Purcell and Dr. Bantock. Dr. Fancourt Barnes: Some Difficulties in the Use of the Curette (a learned discussion). Dr. Halliday: A Case of Glycosuria complicating a Large Ovarian Cyst. Dr. Hanson, of Rome, will exhibit and explain some Roman Antiquities relating to Obstetrics and Gynecology, mostly Votive Offerings dug up in Italy.

NEUROLOGICAL SOCIETY OF LONDON, National Hospital for Paralysis, Queen Square, 5 P.M.

BIRTHS, MARRIAGES, AND DEATHS.

The charges for inserting announcements of Births, Marriages, and Deaths to be paid, which must be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

WILDING—On June 30th, at The Hawthornes, Hindley, wife of W. F. W. Wilding, Medical Officer of Health, of a son, prematurely—survived a short while.

CARR—On May 24th, at Juffa, Ispahan, Persia, the wife of Donald W. Carr, M.B., B.C. Camb. (Church Missionary Society), of a son.

NORTHROP—On June 24th, at Holly Lodge, Norbiton, Surrey, the wife of A. Beauchamp Northrop, M.D., of a son.

MARRIAGES.

RUSSELL—RITCHIE—At the Free Middle Church, Perth, on June 14th, by the Rev J. Calder Macphail, D.D., Friary, assisted by the Rev D. W. Kennedy, Perth, and the Rev A. C. Watt, Cuprie, William Russell, M.D., F.R.C.P.E., to Beatrice Ritchie, M.D., elder daughter of James Ritchie, C.E., Perth.

McKENNIE—NUTTERLAND—At Waterlap, Larbert, on June 27th, by the Rev. Robert Leckie, John McKennie, L.R.C.P. Edin., Kirkby-in-Ashfield, Notts., to Nellie, eldest daughter of the late John Nutterland, Waterlap, Larbert.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

MUSICAL MEMBER writes: Can any member recommend a reliable treatment for excessive perspiration of hands in a violinist and pianist?

Dr. J. W. would be glad to hear of any institution or home in which a woman of feeble intellect would be received on payment of a sum not exceeding £1 weekly.

ELECTROLYSIS OF SUPERFLUOUS HAIRS.

G. asks: How many cells of a Leclanché battery ought to be used for this operation? To which pole ought the needle to be attached? I have been using twelve cells with the patient under chloroform, and still the hairs recur.

* Five Leclanché cells should be used, the needle on the negative wire; for the operation to be successful the needle must enter the hair follicle; if it is made of very fine platinum wire and is blunt-pointed the introduction of it into the follicle is easier than with a stiff sharp needle. Chloroform is quite unnecessary.

ANSWERS.

SARTOR.—We know of no institution which takes male inebriates free or on a very small payment.

MEMBER might do well to apply to the carriage company in question for references to any medical men who have purchased their vehicles.

LAYMAN.—Holds to Mothers for the Management of their Health during the Period of Pregnancy and in the Lying-in Room, by Thomas Hunt, M.D., edited by R. W. Parker, M.R.C.S. (London: Longmans, Green, and Co. 2s. 6d.), would probably meet our correspondent's requirements.

PUBLIC HEALTH.—The holder of a diploma in Public Health would have no prior claim in a legal sense, unless the town or district has a population of 10,000 or more. In any case the diploma ought to carry weight with the electing body as evidence of special knowledge of the kind which the appointment calls for.

W. G.—We know nothing of the composition of this secret "remedy." Some time ago it was reported in the press that the representative of this "remedy" had been fined for passing it off as the genuine of the alleged poisonous character, in one of the counties. Recently there have been published statements to the effect that there have been many relapses.

HARVEY'S WORKS.

Dr. J. R. Williams.—Our correspondent is probably thinking of the *Journal* of the original edition of the *Dr. Harvey's Works*, with translation and memoir. This was published by subscription in December last by Mr. G. Macdonald, 21, Barge Street, Canterbury.

CAMBERWELL PROVIDENT DISPENSARY.

We have received a letter from Mr. James Wyatt, Secretary to the Camberwell Provident Dispensary, complaining of the term "sweating the doctors" being applied to the system of remuneration of the medical officers of that institution. The term "sweating," we believe, is a word of recent introduction, and is hardly understood to mean any more than living in a trade where the trade workers are systematically deprived of what may be regarded as "fair" wages for their work. Presumably, if by any compensation among the public medical practitioners should be desired to accept as remuneration such payments as, for example, those paid by the above institution to their medical officers, it is difficult to see why the term "sweating" should not apply in their case as in the other.

If this institution is a charity it can hardly be considered a provident

dispensary, and other circumstances have to be taken into consideration, but our correspondent labours under a misapprehension if he imagines that "sweating" is not possible in the case of charities, for when these latter are abused, as they too frequently are, "sweating" of the most pernicious kind is the result.

To get so large a sum as £2,000, or £1,000 a year, out of such small payments as those charged to members of this institution must obviously imply a correspondingly large membership. We are free, however, to admit that the dispensary has rules which in one important respect are superior to some other institutions of a similar class. According to Rule 3 the benefits are not to be extended to those whose average earnings exceed £5 a week. The Honorary Secretary speaks of the institution as a charity supported by voluntary contributions, whereas in the rules it is called a provident dispensary. As we have had occasion to point out recently on several occasions, among others, in commenting on the Leicester Dispensary, an institution cannot well be both provident and charitable.

MEDICAL AID ASSOCIATIONS.

C.H.H.—If our correspondent had given any attention to the answers in our columns during the last few weeks he must have seen the subject of his question discussed over and over again. It has repeatedly been stated that medical aid societies are not desirable associations for medical practitioners to be connected with, and the one referred to by our correspondent is, perhaps, the worst of them all.

F.H.M.—If to accept so par cent. of penny-a-week subscriptions for medical attendance on persons regardless of their social and financial condition be derogatory from a professional point of view, especially when these miserable patients are obtained by the wholesale "touting" of the public, including the patients of other practitioners, we cannot but consider the appointment referred to by our correspondent an objectionable one, and should therefore advise him to decline it.

NOTES, LETTERS, ETC.

LUNATIC ASYLUMS AND INHABITED HOUSE DUTY.

THE First Division of the Court of Session at Edinburgh decided last week that the Dundee Royal Lunatic Asylum was liable to be assessed for inhabited house duty on the full value of the institution. This decision was arrived at on the ground that the asylum was not covered by the words of the exemption—"any hospital, charity school, or house provided for the reception or relief of poor persons." It was also held that certain parts of the income of the asylum were of the nature of an endowment. The board of private patients, too, was a difficulty.

THE DENTAL PROFESSION.

DR. HUGH WOODS (Highgate) writes: Mr. Storer Bennett characterises my statement as to unqualified dental practice as "absolutely unfounded" to the knowledge of those really acquainted with the facts, and he considers that I cannot be in a position to form an accurate judgment on the subject. I quite admit that neither I nor Mr. Storer Bennett can form an accurate judgment on the subject. We can only make a rough estimate, as I did in my letter. If Mr. Storer Bennett will give his estimate there will be a more profitable subject for us to discuss than that of my veracity. I do not think the possession of a dental diploma essential to a right judgment on such a subject. I have made special investigations in respect to the question, and have received much information from many dentists. I have also in my possession a sworn affidavit in reference to a large dental concern in London, and I can assure Mr. Bennett I did not make the statement recklessly. He will find that many firms who are carrying on large advertising dental practices pay no regard to the Dental Acts in the employment of their operators. The Dental Acts are almost inoperative as regards penalties against unregistered dentists. If there were any body which would undertake prosecutions in a manner likely to be effective, I would undertake to keep it supplied with cases for a long time to come. There is a dentist in this neighbourhood who has practised as a dentist in open disregard of the Dental Acts since the *Register* was founded. He could have registered, but he did not take the trouble. I may be wrong as to the precise amount of dental work done by unregistered persons; but my statement, instead of being "unfounded," has a very large foundation indeed. Probably some dental readers of the *BRITISH MEDICAL JOURNAL* will support my opinion.

DRY GANGRENE AFTER SNAKEBITE.

DR. MICHAEL G. DOBBYNS (Bursrah, Persian Gulf) writes: The following curious case came under my notice at Bursrah (Bassorah) in September, 1894. An Arab was brought to me suffering from dry gangrene of the left leg, extending to within 2 inches of the knee-joint; the leg was completely mummified. He gave the following history: About two months previously, while working in the gardens at Gerna—the presumed site of the Garden of Eden—which are situated at the junction of the Tigris and Euphrates, he was bitten in the foot by a snake. The local barber was immediately summoned, who tied a ligature tightly round the man's thigh, excited the flesh in the neighbourhood of the bite, and then bled him freely from the long saphenous vein. Having determined on amputating, I placed the patient on a mattress and left the room to get my instruments; but, hearing loud screams proceeding from the room, I ran back, and to my surprise saw a snake about 3 feet long within 10 feet of my patient. My servant who was present got a stick but failed to strike the snake, which made its escape under a pile of date wood. I may mention that this is only the second snake that I have seen in Bursrah after a residence here of over a year. I amputated the limb through the condyles and the patient made an uninterrupted recovery, returning home in four weeks with an excellent stump. Perhaps some of your readers who are authorities on the effects of snakebites may be able to inform me whether the gangrene could be due to that cause or to the more possible one of the barber's ligature.

LETTERS, COMMUNICATIONS, ETC., have been received from:

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	60	4	0
Each additional line	0	0	0
A whole column	1	17	0
A page	5	5	0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage-stamps.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

A CLINICAL LECTURE ON DISEASES OF THE BREAST.

Delivered at the Middlesex Hospital

BY

ANDREW CLARK, F.R.C.S.,

Surgeon to, and Joint Lecturer on Surgery at, the Hospital.

DURING the last few weeks we have had under our observation in Bird Ward no fewer than 9 and in Whithead Ward 2 cases of diseases of the breast, and I take this opportunity of recalling them to your minds and making some observations which I hope may prove useful. The moment a woman notices anything wrong with her breast, whether it be painful or enlarged, or she can feel a distinct tumour in it, she at once begins to get uneasy lest she should have cancer, as there is a widespread idea, and there is certainly some ground for it, that the female breast is one of the commonest seats of cancer. The result is that we see a considerable number of patients with supposed cancer of the breast, who not only have no cancer but frequently have no tumour, and not infrequently have nothing more the matter than neuralgic pains, and this is particularly the case in women of a nervous temperament whose general health has been undermined by a long illness or nervous shock. *Appropos* of this I might mention that it is sometimes difficult to convince a patient that she has not a tumour, as, if a breast is manipulated in a certain way, namely, the gland seized between the thumb and fingers, and compressed, the idea of a tumour is presented to the touch; what is felt being nothing more than the compressed gland tissue. When examining a breast, therefore, you should make it a cardinal rule always to place the hand flat upon it and make gentle pressure against the ribs, carefully feeling every part; in this way you cannot fail to detect a tumour if one be present, and you do not manufacture one if it be not there.

Before detailing the cases, let me enumerate the chief of the abnormal conditions which are presented to us in the breast, some of which are represented in the cases I shall mention. Neuralgia, subacute mastitis, induration left after acute abscess, chronic abscess, cystic disease—and of this there are several varieties, those arising in the ducts of the gland, the simple serous cyst arising in the areolar tissue, and cystic developments in solid tumours being the commonest—and, lastly, solid tumours, which may be divided into non-malignant and malignant. Occasional instances of most varieties of the former class have from time to time been recorded, but the so-called adenoid is that most frequently met with; the majority of these tumours are not, however, pure adenoid growths. Although some of them have been found to consist entirely of imperfectly developed gland tissue, the majority are intermixed with more or less dense fibrous and connective tissue, hence the terms adeno-fibroma, adeno-sarcoma, or, putting it the other way, hard and soft fibro-adenoma; these varieties not infrequently undergo cystic degeneration, and result in the cystic adenoma.

Among the malignant tumours scirrhus is by far the commonest, but soft cancer and colloid are sometimes met with, and a good many cases of epithelioma or duct cancer arising in the columnar epithelium of the ducts have been described. Sarcoma, too, usually of the spindle-celled variety, is occasionally met with.

I will now give you an abstract of each of the eleven cases, and in order not to weary you, shall omit details which are unnecessary for our purpose.

CASE I.—C. B., aged 38, a married woman with one child, noticed a small lump in her right breast early in the year 1882; for two years it enlarged very slowly, but for the last twelve months the enlargement has been more rapid, and she has experienced a painful sensation about it, and the skin has become reddened; she has also noticed that she has been losing flesh. She, however, sought no advice until a fortnight ago, when she went to another hospital, where, she says, she was told that she was not strong enough to undergo

an operation, and was discharged in seven days. No cancer or phthisis could be traced in the family.

On admission we found a retracted nipple, a hard tense tumour, the size of a pigeon's egg, in the right breast immediately below the nipple; the skin was red and firmly adherent to it, but it was freely movable over the chest wall, and no glands were found implicated. The diagnosis was scirrhus. The breast was removed, a good deal of the skin having to be sacrificed, which somewhat retarded recovery, as it was impossible to close the wound completely, but the patient left the hospital quite well six weeks after the operation.

CASE II.—J. M., aged 55, also a married woman, who had had two children, the youngest 27 years old, observed about four months ago that her right breast was larger than the left, and the nipple was drawn in. From that time to the present the enlargement has been increasing, but she has suffered no pain; no cancer or phthisis in the family. On admission the right nipple is seen to be retracted; a hard tumour the size of an orange can be felt in the upper segment of the breast, which is not adherent to the structures beneath, nor is the skin adherent to it. An indurated cord can be felt leading into the axilla, where there is decided glandular enlargement. The diagnosis here was scirrhus. The breast and axillary glands were removed in the usual way. The wound was completely closed except in the angle of the axilla, where a drainage tube was inserted. The greater part of the wound healed by the first intention, but recovery was retarded by some suppuration in the axilla. This patient, however, left the hospital quite well six weeks after the operation.

CASE III.—S. B., aged 38, married, three children, youngest 9 years old. She first felt a lump in her right breast when she accidentally touched it; this was, as far as she can remember, about a year ago; it has never given her any pain, and she has enjoyed fairly good health, but she states that the tumour has perceptibly but not rapidly increased in size. No history of cancer in the family. A brother died of phthisis. On admission, the right breast was obviously larger than the left; the right nipple was on a lower level than the left nipple, but was not retracted, and immediately below it a tumour about the size of a Tangerine orange could be felt. It was said not to be painful, but was very tender, and ached for some hours after manipulation. It was hard and inelastic, moved on the subjacent structures and the skin moved over it, and there were no enlarged glands to be felt. The diagnosis was doubtful, so, after the patient had been put under an anæsthetic, prepared for whatever was necessary being done, an incision was made into the centre of the lump. This settled the diagnosis immediately—namely, scirrhus—so the breast was removed in the ordinary way, the edges approximated, and firm pressure made on the wound by strapping. The wound healed by the first intention, and the patient left the hospital quite well three weeks after the operation.

CASE IV.—E. R., aged 44, married, three children, youngest aged 7, noticed a lump about the size of a walnut in the lower quadrant of her right breast. For a month it appeared to undergo no change, when it suddenly, without any cause that she knows of, became painful and got a little larger, so she came to see me, and I found an indurated swelling, adherent all round, which I believed to be inflammatory, and recommended treatment accordingly. A fortnight's treatment, however, resulted in no change except an increase in pain. Accordingly, I punctured the swelling with a negative result and advised the patient to go to the hospital. This, however, she would not consent to do till another month had elapsed, when she went and was admitted. During this time there had been practically no change in the tumour, and the report on her state on admission says: There is a rounded tumour in the lower quadrant of the right breast, circumscribed and abrupt above, but its edge ill defined below. It is hard and brawny to the touch, adherent to the pectoral fascia and to the skin, which is reddened for some distance and almost on the point of ulcerating at the most prominent part. One enlarged gland can be felt in the axilla, but it is not hard. No history of cancer or phthisis in the family. The diagnosis here was a little doubtful; it was obviously a solid growth, and so I decided to remove it, leaving the breast. This was done by a vertical elliptical incision, and though the naked-

eye appearance was something like scirrhus, a microscopic examination was necessary to determine its nature, which has proved it to be so. It was not possible to close the lower part of the wound, owing to the necessary sacrifice of some skin, but the patient made a good recovery and left the hospital a month after the operation, the wound well healed.

CASE V.—M. C., aged 70, married, five children, the youngest 23 years old. A month before admission she noticed that her right nipple was drawn in, and on putting her hand to the breast she felt a hard lump which seemed to her, after feeling it a few times during the last month, to be increasing in size, and for the last week she has experienced occasional pains in it. There is no history of cancer or phthisis in the family. She remembers having a swelling in the same breast after her first child, which after a time burst and discharged matter. On admission the following was her condition: the superficial veins on the right side of the chest are enlarged, the right nipple is retracted, and a hard nodular mass can be felt in the lower and outer quadrant of the breast. It is not adherent to the structures beneath, the skin is slightly puckered over it; no enlargement of lymphatic glands can be detected. Diagnosis, scirrhus. Treatment: Excision of the gland in the usual way, and it is noted that there was only one vessel requiring a ligature; the edges of the wound were brought into good apposition, a drainage tube inserted, and the wound dressed with dry dressing. The dressings were reapplied the next day, as a blood-stained discharge had come through them; the wound looked healthy, so the tube was removed and the dressings reapplied. The patient left the hospital quite well three weeks after the operation.

CASE VI.—A. A., aged 36, married, no children, gave the following history: Over two years ago she received a blow on the right breast, and a few months after she noticed a lump the size of a pea in the situation of the blow; this gradually enlarged, and in June, 1893, she consulted a doctor. This is the first accurate date she can give, but she thinks at that time she had had the swelling about six months. An incision was advised, which was made, and the tumour disappeared, but gradually formed again, and in March, 1894, the breast was removed. No history of cancer or phthisis in the family. On admission there was a horizontal scar 7 inches long over the right mammary region, and about a third of the distance from the inner end a swelling the size and shape of a Tangerine orange. The greater part of the swelling was hard but the inner part was softer and there was an indistinct sense of fluctuation communicated on manipulation; it was freely movable over the subjacent structures and the skin was movable over it. No enlarged glands could be detected. The diagnosis here was recurrent cystic adenoma, the old-fashioned sero-cystic sarcoma. Its removal was advised and carried out by elliptical incisions, when it was found to be a papillomatous cyst. The wound was dressed with dry dressing and strapped firmly, and the patient left the hospital quite well a fortnight after the operation.

CASE VII.—M. A. H., aged 58, married, no children, noticed a lump about the size of a walnut in her right breast between three and four months before admission. It has been gradually increasing in size since that time but has never given her any pain; no family history of cancer or phthisis. On admission the breast was observed to be very small. A tumour the size of a Jaffa orange occupies the upper and inner quadrant of the right breast; it is elastic, and gives a doubtful sense of fluctuation; at one spot the skin is slightly discoloured and adherent, the tumour is freely movable over the chest wall, the nipple is not retracted, there are no enlarged glands to be felt. Diagnosis, cystic disease. The treatment decided on was removal, which was accordingly done in the usual way. A drainage tube was inserted into the lower angle of the wound, and removed after twenty-four hours, and dry dressing applied. The patient had no untoward symptoms, the wound healed rapidly, and she left the hospital convalescent in less than three weeks after the operation.

CASE VIII.—M. B., aged 44, widow, no children, gave the following history. A fortnight ago, while washing, she noticed a small lump in her breast. It was tender to the touch, and the skin over it was slightly reddened; it has not altered in character since first observed but is the seat of occasional shooting pains, and is a worry to the patient. Her mother and her

mother's mother died of cancer, and her father's father, brother, and herself suffer from epileptic fits; no history of phthisis. On admission there is a small, ill-defined lump in the outer quadrant of the right breast, movable with the breast over the subjacent structures and not adherent to the skin, which is slightly reddened over it. It appears to be tender, and this tenderness extends into the axilla, though no enlargement of glands can be detected. Diagnosis, subacute mastitis. After a week's treatment the patient left the hospital, the swelling having entirely disappeared.

CASE IX.—M. A. C., aged 85, widow, six children, youngest 50 years old, noticed that five years ago her left nipple was retracted, but she had no pain, and took no heed of it until about twelve months ago, when the skin became ulcerated; she then sought advice, and was given something to apply to it, but the ulcer spread, and nodules formed in the neighbourhood. On admission, in the site of the left breast was an ulcer about the size of a four-shilling piece adherent to the subjacent tissues; the nipple could not be seen, and there was a hard nodule near the centre of the ulcer; there was a thin puriform discharge, and several glands could be felt in the axilla. Diagnosis, scirrhus; treatment, palliative.

CASE X.—E. B., aged 45, single, first noticed a swelling in her left breast about the middle of February last; it was slightly painful and tender. After a month she sought advice, and an operation was recommended; the swelling continued to increase in size until a fortnight ago, since which time it has remained stationary. On admission both breasts are very small; a rounded tumour, the size of a small Tangerine orange, can be felt in the upper and inner quadrant of the left breast; it is elastic and semifluctuating, neither adherent to the skin nor to the tissues beneath; no enlarged glands in the axilla. Diagnosis, cyst; treatment, excision of gland. There was an unusual amount of hæmorrhage for so small a breast, but it was completely stopped by pressure and catgut ligatures, the edges of the wound well brought into close apposition, dry dressings applied, and over this broad strips of strapping. The wound healed by the first intention, and the patient left the hospital convalescent sixteen days after the operation.

CASE XI.—R. M., aged 66, spinster, noticed a small hard nodule in her left breast about twelve years ago. She says it looked and felt like a finger nail implanted there; she suffered no pain from it, and sought no advice. It gradually increased until it has attained its present condition, and lately the skin has been discoloured. No cancer or consumption in the family; she herself has been suffering from rheumatism for the past four years more or less severely, and is now quite helpless on account of it, being unable to move her legs or arms without great pain. There is a warty-looking growth, the size of a large orange, in the upper and outer segment of the left breast; it is adherent to the skin, but moves freely over the subjacent structures; no retraction of nipple, and no enlarged glands. Diagnosis, duct cancer. The patient objecting to operation, it was decided to treat it with Fell's paste, and now, three weeks after the commencement of treatment, the growth has nearly sloughed off.

Such, then, is a brief account of these 11 cases, 7 of which were cancer, 3 cystic disease, and 1 mastitis. Commenting upon them as a whole, although it would be unfair to base statistics on so few cases, I think that, from 11 chance cases, coming, as they have done, so close upon one another and not selected in any way, we are entitled to draw some general conclusions. We notice first that cancer is about twice as common as all other diseases of the organ, excluding of course acute inflammation; secondly we notice that the diagnosis in all but 3 presented but little difficulty as between malignant and non-malignant disease, the exact nature of the latter not always being so easy to settle, and in 1 of these 3 (VIII) twenty-four hours' watching confirmed the diagnosis. Then we notice that age does not help us much in determining whether we have a case of malignant disease, two patients aged 38 having cancer and the patients with cystic disease being respectively aged 58 and 45. Then we observe that the only case in which there is a history of malignant disease in the family was the case of mastitis, and in not one was there a history of tubercle. We observe, too, that nearly all enjoyed good health till the time of their attack. Then in every case the lump or the retracted nipple was

what drew the patient's attention to there being something wrong, and in only 2 of the cases of cancer was pain a prominent symptom at any time. In 3 of the 11 cases the disease appears to have lain dormant for a year or longer, and in only 1 can the patient suggest any cause, either for the original development or for the activity of the growth, and the cause given in 1 of the cyst cases was a blow some months previously. In 3 of the cases, and these were all cancer, retraction of the nipple was an early symptom. In no case was disease of the nipple recorded as an antecedent condition.

I have said that in only 3 of these cases was there any difficulty in coming to a conclusion as to whether the disease was malignant or not, and we may quickly reduce that to 2, because in 1, that of subacute mastitis, although on first examining the patient there was found an ill-defined non-circumscribed lump in the breast, tender to the touch, and this tenderness extending into the axilla, and a history of darting pains and a marked family history of cancer, the course of the disease had been too rapid for an actual tumour to have developed, and the idea of an inflammatory swelling was uppermost in our minds, which a few hours' observation proved this to be. The 2 cases that presented real difficulty were Nos. 3 and 4, both of which turned out to be malignant, and in the case of No. 4 it was only a microscopic examination that determined the nature of the disease. To recognise malignant disease in its early stage is of the utmost importance, because when it has spread to the adjacent glands the chance of cure is very much lessened even if they be thoroughly removed, and though some may say, if in doubt operate, I think we should, to say the least, feel dissatisfied with ourselves if we removed a breast and then found that we might have saved it. What then are the conditions most likely to be mistaken for cancer? I think they are the following—chronic mastitis, chronic abscess, cystic disease deep in the breast, and sometimes, but not often, fibro-adenoma.

The chief signs of cancer in the early stage are a patient over, or at any rate not far from, 40 years of age, often one whose health has previously been excellent, a rapidly enlarging diffuse indurated, inelastic tumour in the breast, sometimes attended with lancinating pains, but often painless, sometimes retraction of nipple or the level of the two nipples not the same. In some cases when it is deeply seated the breast does not glide freely over the subjacent tissues, and when it is superficial the skin gets early adherent, and often on manipulation the skin puckers; sometimes, even fairly early in the disease, there is enlargement of the axillary glands. All the above signs may be present in the first three conditions just mentioned, and in not a few it is impossible to diagnose between chronic mastitis and scirrhus without resorting to an incision; a puncture is not enough. In abscess and cyst there is generally more elasticity, and the centre is softer and more elastic than the periphery. In abscess there is often some oedema of the adjacent tissues as well, and tenderness along the line of the lymphatics and in the glands of the axilla, and in these cases a puncture should be made, and may be sufficient to confirm the diagnosis. Fibro-adenomata generally occur in younger people; they are also more distinctly circumscribed, and are more movable. In these two cases we are discussing one was painful the other not; neither had a retracted nipple, but in one the level of the two nipples was altered the other not. In one the tumour was freely movable and the skin moved over it; in the other the reverse was the case; in one the glands were not affected in the other they were. In neither was there a history of malignant disease in the family. In one the previous health had been excellent in the other indifferent; in one the history extends over a year in the other about two months. You see how the symptoms differ and yet they both turned out to be malignant.

In the one case an incision into the tumour at once revealed the nature of the disease, the peculiar hard cracking sensation communicated to the fingers the moment the knife entered the tumour being sufficient to make the diagnosis a certainty, but in the other case, after removal and an incision, the diagnosis was not certain, and it is only the microscope that has settled the question for us. Had time permitted I should have liked to have compared Case iv and those of non-malignant disease with a view to discussing the differential diagnosis of non-malignant tumours. I may, how-

ever, have an opportunity of doing that on some future occasion.

I wish now to say a few words on the treatment. Eight of the cases were subjected to operation, and the operation is a perfectly safe one; death is very rare even when the axilla is freely opened up, and union by the first intention, at any rate of the greater part of the wound, is the rule. All the patients got well without a bad symptom, the time required for the healing process varying from sixteen days to six weeks. In 1 of the cases the axillary glands were removed, and in 2 it was necessary to sacrifice so much skin that the edges of the wound could not be approximated, and it was these that took the longer time to heal, and in which union was accompanied by suppuration. Healing was most satisfactory in those cases that were healed by dry dressing and strapping firmly applied, great care being taken to stop all oozing before the dressings were put on. In those cases in which we could not satisfactorily apply the strapping so as to make firm pressure, a drainage tube was used, and removed at the expiration of twenty-four hours. They were all dressed with our usual dry dressing: the skin was dusted with iodoform, and covered with antiseptic gauze and wool.

The rule that I have adopted in regard to the extent of the operation is to remove the tumour when non-malignant and the breast when the disease proves to be malignant, as well as the axillary glands, if they are affected, but you may have observed that in these 8 cases there were 2 exceptions to this rule. In the one (Case iv) I left the breast, though the disease was scirrhus, removing only the tumour. The reason of this was that at the time of the operation I could not satisfy myself of the nature of the disease, and, though the principle when in doubt remove too much rather than too little, is a good one, in this case I felt satisfied in removing the tumour only, as it appeared to me that none of the diseased tissue remained. Time will prove whether this is correct. I saw the patient last week—a month after she had left the hospital—and up to that time everything was satisfactory, but I shall watch her carefully, and in the event of any recurrence in or near the scar I shall advise a radical operation. In Case x, although the disease was not malignant, the breast was excised. The reason of this was that the breast was very small and the tumour involved practically the whole of it. One more remark, and that is about Case xi. Why was not that excised instead of being treated by Fell's paste? I wished to excise it, and believe that would have been the best course, but the patient absolutely refused any operation, so the next best thing seemed to be the treatment adopted. She is still in the hospital, and you can see now in the place of the tumour, which has sloughed off, a healthy ulcer. In certain cases, such as this one, that method of treatment is effectual, though it is slower and more painful.

HUNTERIAN LECTURES

OF THE

EXPERIENCE OF ST. GEORGE'S HOSPITAL IN LAPAROTOMY:

EXCLUSIVE OF GYNÆCOLOGICAL OPERATIONS,
FROM 1888 TO 1894 INCLUSIVE.

Delivered at St. George's Hospital Medical School

By T. HOLMES, F.R.C.S.,

Consulting Surgeon and Treasurer to the Hospital.

LECTURE II.—CHOLECYSTOTOMY: LAPAROTOMY FOR TUMOURS AND FOR GASTRIC ULCER.

THE first topic of to-day's lecture is cholecystotomy, our recorded experience of which has been remarkably small, only three cases being noted; but I believe that there have been other successful cases which have not been recorded. In all three cases the operation was, as an operation, perfectly successful, but in the one which first occurred, that of a woman under Mr. Bennett's care, it was useless, as after the extraction of two gall stones from the bladder, it was found that a

malignant tumour lay behind, involving the common bile duct. The patient went home after recovering from the operation, and died there from the progress of the cancer about three months after. The other two were striking examples of the success of this operation in suitable cases. The first is recorded in the *Lancet* for May 23rd, 1891. The other patient was an elderly woman, deeply jaundiced, who was operated on by Mr. Bennett last year. After she had been under medical treatment for a month with no benefit, numerous stones were removed, and the permeability of the cystic duct was established. Some polypous fragments of a suspicious appearance were removed from the interior of the viscous, but were judged on microscopic examination to be merely the result of irritation of the mucous membrane. The edges of the wound in the gall bladder were sown to the abdominal parietes. The jaundice rapidly disappeared, and the wound was nearly healed on her discharge about five weeks afterwards.

The best summary with which I am acquainted of the indications for surgical operations on the gall bladder and bile ducts is in a paper by Mr. Mayo Robson, read at the International Medical Congress at Rome, and published in the *BRITISH MEDICAL JOURNAL* for April, 1894. This paper gives the results of 78 operations in Mr. Robson's own practice, of which only 4 proved fatal. In many cases the permanence of the cure had been ascertained. Mr. Robson's list contains not only cases of simple cholecystotomy, but other more complicated proceedings, such as the formation of anastomosis between the gall bladder and intestine (cholecystenterostomy), the crushing of the stones in the bladder or duct (cholelithotripsy), the incision and suture of the common duct (choledochotomy), and the excision of the gall bladder (cholecystectomy).

Mr. Mayo Robson's experience appears to me to show that cholecystotomy is an operation which in skilful hands involves only slight danger; and the operation will in all probability be much more extensively used in the near future, to relieve the atrocious sufferings sometimes caused by gall stones; while the other more complicated proceedings, though some of them are no doubt highly dangerous, have their own field of application, and ought to be carefully studied by those who may be called upon to treat such emergencies.

Our own limited experience certainly favours such a conclusion.

I will next speak of laparotomy for tumours. The following is a tabular statement of our cases:

Laparotomy for Tumours.

Name.	Age.	Date.	Nature of Tumour.	Surgeon.	Result.	Remarks.
1. J. K.	—	Nov., 1889	Hydatid of liver	Mr. Bennett	R.	—
2. J. H.	—	Jan., 1891	Hydatid in pelvis	Mr. Howard	R.	—
3. A. O.	44	Sept., 1891	Hydatid of liver	Mr. Dent	R.	—
4. R. H.	—	Oct., 1891	Hydatid of gall bladder	Mr. Bennett	R.	—
5. M. L.	—	Feb., 1891	Hydatid of liver	Mr. Pick	D.	—
6. E. A.	34	Nov., 1890	Hydatid of liver, ruptured	Mr. Turner	D.	—
7. W. S.	34	Feb., 1894	Pancreatic cyst	..	R.	—
8. J. P.	—	May, 1891	Hydronephrosis	Mr. Bennett	R.	—
9. A. C.	24	April, 1890	Uterine fibroids	Mr. Dent	R.	—
10. A. F.	30	" 1890	Extrauterine foetation	Mr. Pick	D.	—
11. C. M.	5	May, 1890	Glandular tumour of mesentery	..	D.	—
12. A. G.	—	Aug., 1890	Malignant tumour in peritoneum	Mr. Turner	D.	—
13. R. T.	55	Nov., 1890	Malignant tumour in peritoneum	Mr. Bennett	R. from operation	—
14. J. B.	—	Dec., 1891	Malignant tumour of umbilicus extending inwards	..	D.	—
15. M. H.	50	March, 1892	Cancer of liver and gall bladder	Mr. Howard	D.	—

There were then 4 cases of hydatid tumours—3 in the liver, and 1 in the pelvis, which were operated on promptly, and recovered. 1 of hydatid in the liver, which was not operated on till after prolonged treatment by tapping, which died, and 1 of hydatid of the liver in which the patient

refused operation and left the hospital, but soon afterwards returned in a collapsed state from rupture of the tumour. She was then operated on unsuccessfully. Closely connected with these is the following very successful case of laparotomy for pancreatic cyst. Here, a man, aged 34, was admitted, under Mr. Turner's care, with a prominent fluctuating and obviously cystic swelling in the epigastrium, separated from the liver by an area of resonance. The symptoms had lasted for nine months and had become rather threatening, so that operation was necessary. The incision was made in the left linea semilunaris. This revealed nothing in front of the omentum, the fluctuating tumour lay behind that structure. It was explored with a needle and then aspirated, 37 ounces of dark-coloured fluid being withdrawn. The cyst was then opened sufficiently to allow the finger to explore its interior, which was smooth, but a hardish mass could be felt lying on the vertebral column. This was left undisturbed, and the opening in the cyst wall fixed to the abdominal wound and a drainage tube inserted. Everything went well except for some discomfort due to the necessary tension on the sutures. The interior of the cyst suppurated and gradually filled up, the tube was withdrawn in a month, and the patient soon afterwards discharged.

Careful and elaborate analysis of the fluid was made by Mr. Latham. It proved almost identical with that of a pancreatic cyst in the *Roy. Med. and Chir. Trans.*, vol. lxxiv, and left no doubt of the pancreatic origin of the cyst.

The number of such operations which have been successfully performed is as yet small. An interesting example, and one very similar to the above, was published by Dr. Newton Pitt and Mr. Jacobson in the *Roy. Med. and Chir. Trans.*, vol. lxxiv. The whole question of the origin, diagnosis, and treatment of these cases is very interesting, and we may hope to have a treatise on this subject from the surgeon who operated in this instance.

I do not quite know how to classify the following interesting case of an operation for hydronephrosis, which is, I believe, quite unique.

J. P. was admitted May 12th, 1891, under Mr. Bennett's care, on account of pain in the left loin and profuse renal hæmorrhage. The left kidney was of large size. It was explored through the loin on June 1st, and found to be hydronephrotic. There was no stone. A drainage tube was inserted. On June 25th, repeated attacks of bleeding from the kidney having occurred, both into the bladder and from the lumbar wound, the patient was nearly moribund. Laparotomy

was performed with a view of removing the kidney, but this proved impracticable, as the patient was too weak to bear the operation. A ligature was therefore tied round the renal vessels. He rapidly recovered, and is now in good health, but with a permanent urinary fistula in the loin. A second

attempt was made to remove the kidney, but sudden collapse came on, and brought the attempt to an end.

This list of laparotomies for tumours of various kinds I think enforces the observation that I made in my first lecture, that the operation is seldom prejudicial to the patient's prospect of recovery; but that its postponement is often so. This is forcibly shown by the contrast between the complete recovery of the first four patients with hydatid, in whom the operation was timely performed, and the death of the sixth patient from her unlucky refusal of operation. Again, who can doubt that the patient with pancreatic cyst would have died but for the operation?

I do not, of course, go so far as to assert that the operation involves no danger, and in the solitary case of the third patient with cancer, it may have hastened by a few days the inevitable end of a painful and necessarily fatal disease.

My next topic is laparotomy for the cure of gastric ulcer.

None of the wonderful developments of modern surgery, or rather, I should say, "medico-surgery," has struck me personally with more admiration than the bold proposal to cut down on the stomach in cases of perforating ulcer, and by sewing up the rent (or, when that is impossible, by attaching its edges to the abdominal wall) save the patient from the death which is otherwise inevitable. I well recollect that the first *post-mortem* examination at which I ever assisted, when quite a young student, was on a case of this sort, where a young woman, never known to have been seriously ill before, died very shortly after a hearty meal. In a paper on the subject published by Mr. J. W. Taylor¹ it is shown that the average period of survival after perforation into the peritoneal cavity is twenty-four hours. This refers to free or sudden perforation, but there is a tolerably large class of cases² in which the ulcer perforates slowly, and the edges of the hole are fenced round by adhesions, so that a subphrenic cavity is formed, bounded usually by the stomach, the falciform ligament and liver, the spleen, the diaphragm, and the adhesions. In such cases life may be prolonged for an indefinite period, which, however, is not usually a long one. The circumscribed cavity will almost certainly burst into the peritoneum, its size being liable to sudden increase by gas poured into it from the stomach, when the adhesions are likely to give way, and thus general and probably rapidly fatal peritonitis is set up. Again, the inflammation is very liable to be transferred to the thorax, either by suppurative making its way through or behind the diaphragm, or by the absorption through the lymphatics of the diaphragm of irritating matters from the subphrenic cavity. In 7 out of 10 cases recorded by Drs. Penrose and Lee Dickinson³ this complication had occurred. In these cases, therefore, laparotomy is

urgently indicated in order that the cavity may be opened, its edges stitched to the abdominal incision, and its contents drained. This having been done, the gastric ulcer may be trusted to heal; or, as Mr. Haward says, if the adhesions have completely given way, or a large opening is found into the general peritoneal cavity, it may be right to attack the ulcer directly and treat it by suture, or attach it to the abdominal parietes.

All this is also true of duodenal ulcers. They may perforate acutely or may lead to a subphrenic cavity, the boundaries of which are usually somewhat different to those of the cavity caused by a gastric ulcer, but which is otherwise indistinguishable from it.

There are some subordinate points in the treatment of these cases which only further experience can clear up. One of the most important is how to prevent that "pocketing" of the contents of the cavity backwards, between the spleen and the diaphragm, on which both Mr. Haward and Drs. Penrose and Dickinson lay stress, and which seems to me to have had much to do with the fatal issue in some of the cases which nearly approached success, such as No. 5 in the following list. A counter-opening here, at the time of operation, if feasible, would seem to afford a considerable safeguard to the patient, as Mr. Haward has suggested. I append a table of cases.

I will give you the leading facts of the 3 cases of free perforation. The first is the well known case published in the *Clin. Trans.*, vol. xxvi, p. 179, by Dr. Lee Dickinson and Mr. Haward. The woman had clear symptoms of perforating gastric ulcer and peritonitis, and was operated on as soon as possible after admission, about fourteen and a half hours after the occurrence of the perforation, the incision being made in the linea alba. Turbid fluid and gas were found in the peritoneal cavity, and lymph in the neighbourhood of the stomach, but the peritonitis did not seem to have extended widely. The locality of the perforation could not be exactly determined at the operation, but was afterwards ascertained to be on the anterior surface, about 3 inches from the pylorus, near the lesser curvature. Much rotation of the stomach downwards and forwards was required in order to bring the ulcer in contact with the laparotomy wound. There was too much thickening of the walls of the stomach to allow of their inversion so as to bring the coats together over the edges of the ulcer, so the perforation was stitched to the wound and a drainage tube inserted, the peritoneal cavity having been carefully washed out. She survived for six weeks, and when she died the subphrenic cavity was almost obliterated, but the gastric ulcer had not healed. Three days after the operation "that curious complication" came on, says Mr. Haward, "which has been observed in connection with so many cases of gastric ulcer—namely, inflammation and suppurative of the parotid glands,"⁴ but save this she had nearly recovered. She died from abscess in the left pleura and multiple abscesses in the left lung, not apparently con-

¹ *Brit. Med. Rev.*, xxvi, 185.
² In our list the number of cases of sudden perforation is much greater than those of limited cavity, but this is accidental. Dr. L. Dickinson, in a search through fifty years of our *post-mortem* records, found 21 examples of free perforation (12 from gastric and 9 from duodenal ulcer), and 24 in which the suppurative from the same cause was more or less limited; of these latter only 1 was duodenal.—*BRITISH MEDICAL JOURNAL*, February 3rd, 1894.
³ *Clin. Trans.*, vol. xxvi.

⁴ The same complication has been recorded in other abdominal cases, as in one of successful laparotomy for kinking of the bowel, under Mr. Rouse's care, to be mentioned in the next lecture.

Laparotomy for Perforated Ulcer of Stomach or Duodenum.

Name	Age.	Date.	Nature of Case.	Surgeon.	Result.	Remarks.
1. M. N.	36	Dec., 1869	Gastric, free perforation	Mr. Haward	D.	Ulcer sewn to wound; died six weeks after from suppuration in pleura and lung.
2. E. G.	41	July, 1894	" " "	Mr. Bennett	R.	Ulcer sewn up; recovered without suppuration.
3. C. M.	27	Dec., 1894	Duodenal, free perforation	Mr. Sheld	D.	Ulcer sewn to wound, died, operation too late, when dying.
4. A. A.	26	Oct., 1891	Gastric, subphrenic cavity	Mr. Haward	D.	Pleurisy.
5. L. J.	21	Jan., 1893	" " "	Mr. Pick	D.	Survived nearly eight weeks; gastric ulcer healed; suppurative perforating the diaphragm and reaching the lung.
6. J. G.	—	Mar., 1892	" " "	Mr. Turner	D.	Multiple gastric ulcer; also had peritonitis and pleurisy.
7. E. P.	19	Mar., 1893	" " "	Mr. Dent	D.	"
8. H. E.	43	May, 1893	Subphrenic cavity, origin not ascertained	Mr. Rouse	R.	Recovered rapidly.
9. M. M.	27	July, 1893	Gastric, subphrenic cavity	Mr. Pick	D.	Died two months after operation from empyema, gastric ulcer healed.
10. F. J.	22	Mar., 1894	" " "	Mr. Dent	D.	Died third day; general peritonitis and left pleurisy.
11. F.	25	Nov., 1893	" " "	Mr. Bennett	R.	Recovery retarded by pleurisy.
12. H. H.	27	Nov., 1894	" " "	Mr. Pick	D.	Multiple gastric ulcer.
13. F. H.	26	Nov., 1893	Subphrenic cavity	Mr. Bennett	R.	Recovery retarded by pleurisy.
14. W. H.	25	June, 1894	Duodenal, subphrenic abscess	Mr. Sheld	D.	There was general peritonitis also, it was necessary to incise the distended bowel, and secure it.

needed with any general septicæmia, but resulting from the absorption of irritating matters from the cavity by the lymphatics of the diaphragm. Mr. Haward's observations on this case are of the deepest interest, and although the patient died, the operation was of great importance as showing clearly the perfect possibility of success.

The next case was a brilliant success: it was that of E. G., aged 41, admitted April 5th, 1894, under Mr. Bennett's care. She had been seized suddenly at 2 p.m. with violent pain at the umbilicus. There was no sickness. On admission she was much collapsed, with evident symptoms of peritonitis, and was operated on at once at midnight, nine to ten hours after the access of pain. The incision was made in the middle line. Food was found in the abdominal cavity, and after careful search an opening the size of the little finger was found in the posterior wall of the stomach. The hole was stitched up and the cavity of the peritoneum thoroughly flushed out with warm water. She went on well, was fed by the rectum for four days, then with a tablespoonful of milk hourly. The nutrient enemata were discontinued in a week, and in a month she was able to leave her bed, and left the house on May 24th.

The third case was that of a woman, aged 27, who was admitted on December 21st, 1894, with symptoms which were not so marked as to lead to a confident diagnosis, so that some delay took place in the operation (by Mr. Shield), which was not performed till the day after admission, about two days after the perforation took place and when the patient was in fact dying. General peritonitis was found, and the edges of the perforation, which was in the duodenum, were stitched to the wound.

The chief lesson of this case is the necessity for prompt operation. The diagnosis on admission lay between perforated gastric ulcer and peritonitis from tubal suppuration, and had an exploratory operation been performed earlier there might have been a fair prospect of recovery.

For the cases of gradual perforation, leading to the formation of a cavity beneath the diaphragm (the so-called sub-phrenic pyopneumothorax*), which have been treated by laparotomy, I must refer you to the table.

I am not quite clear what the published results of laparotomy for gastric ulcer hitherto have been. On March 18th, 1894, Mr. Morse, of Norwich, read a very interesting paper at the Royal Medical and Chirurgical Society on a successful case of his own, and appended a list of 16 cases, including his own, of which only 2 had recovered. This list, however, was imperfect. In the discussion which ensued, Mr. Barwell stated that 24 cases had occurred to his knowledge, but gave no addition to the list of recoveries. Mr. Page, however, while referring to 2 fatal cases in his own practice (which were, I presume, included in Mr. Barwell's 24), read a communication from Mr. Macaron, of Carlsruhe, who had operated three times and once with success. If this were correct, we should have 3 recoveries out of 27 cases. In the *Lancet* for 1895, vol. i, p. 545, however, Mr. Jowers gives a list of 25 published cases, in which the cases recorded by Dr. Ewart and Mr. Bennett and that of Mr. Haward are included; of these 16 died, 8 recovered, and in 1 the result is not recorded.

Our own experience of laparotomy for gastric ulcer is as follows:—There were 3 cases of acute perforation—1 perfectly recovered, 1 nearly recovered but died of parotid abscess and abscesses in the left lung and pleura, the result, doubtless, of a condition of local septicæmia, which was caused in all probability by absorption of purid matters from the peritoneal cavity through the lymphatics of the diaphragm. The great probability of this event is pointed out

by Mr. Haward in his paper on this case, and is forcibly used by him as a motive for not delaying operation in any case of supposed perforation of the stomach. The third case was operated on too late. The perforation was in the duodenum, not the stomach. The number of cases of chronic perforation with subphrenic cavity was 11. In one of these also the ulcer was duodenal, and the cavity had burst into the peritoneum; 3 recovered.

This is, I submit, a very gratifying result, but only if regarded as a beginning. That such cases will be treated with a far larger proportion of success in the future (and I would say in the very near future), I am confident. The diagnosis is becoming much better understood, and it is also becoming much plainer that the risks of an exploratory operation which may negative the diagnosis are not nearly so great as the fatal consequences of delay would be in a case of real perforation. I have already alluded to a case in which such an exploration was made, and in which the symptoms disappeared and the patient recovered.

There are many details of the operation in cases of free perforation which are still unsettled, as indeed must be expected in so novel a proceeding; such as the best place for the incision, the best way of finding the perforation, and of dealing with it when found, and the desirability of washing out the stomach through the perforation. As far as I am able to form an opinion, I think the limited experience hitherto recorded goes to show that the incision is best made in the middle line; that the anterior wall of the stomach should be very carefully explored before taking the necessary steps to gain access to its posterior surface; that it is unnecessary to excise the ulcerated part; that it is far better to sew up the opening than to attach its edges to the wound; and that the advantages of washing out the stomach through the ulcer do not compensate its disadvantages in prolonging and complicating the operation.

But though we look forward with confidence to much better results for the treatment of gastric ulcer in future, it would be childish to ignore its essential difficulties. The preparations before you show what a formidable extent of the stomach wall is sometimes affected, the size of the perforation—in some cases far beyond anything that could be brought together by sutures—the great vessels which may lie near the opening, and the frequency of multiple ulcers; while Mr. Haward's case above related shows that the tissue of the stomach may be so thickened by inflammation round the ulcer that its inversion for the purposes of the suture is impracticable. Some of these complications are beyond the surgeon's control, and must remain as permanent dangers both before and after operation. In ulcers of great size, and in those accompanied by extensive infiltration of the stomach wall, nothing can be done except to attach the stomach to the wound, and this no doubt may be successful; but it cannot but be accompanied by greatly increased risk. The most promising cases must be those in which the ulcer is of small size, and easily sewn up, and in which the contents of the peritoneal cavity can be completely washed out. In such instances, as Mr. Bennett's case shows, recovery may be complete, rapid, and permanent. And this really seems to me the most wonderful of all the surgical miracles of our time.

* In two of our own cases and one of those published by Drs. Penrose and E. Dickinson there were three ulcers.

The Canadian Medical Association will hold its annual meeting this year at Kingston, Ontario, on August 28th, 29th, and 30th. Sir Charles Tupper, M.D., the first President of the Association, is expected to be present.

At a recent meeting of the American Medical Editors' Association in Baltimore, Dr. George M. Gould, editor of the *Philadelphia Medical News*, was elected President, and Dr. A. H. Ohmann-Dumond, Vice-President.

SUCCESSFUL VACCINATION.—Mr. Alfred E. Vaughan, Public Vaccinator for the Hartington District of the Nantwich Union, has for the second time been awarded a grant for efficient vaccination.

MR. W. KAYE PARRY, A.M. Inst.C.E., of Dublin, has been awarded a Mullins Gold Medal by the Institute of Civil Engineers of Ireland for a paper on the application of recent advances in the study and treatment of sewage.

* I do not want to waste time over verbal criticism, but may perhaps be pardoned for expressing a hope that our medical vocabulary may provide some more expressive and more appropriate word for this condition than "pyopneumothorax subphrenicus," a term which in spite of its "learned length and thundering sound" seems to me incorrect and misleading. The collection of air and fluid is no doubt partly under the ribs, and in that sense might be said to be in the "thorax," just as the liver lies between the thorax and abdomen, and hence if there is no doubt, though they may have displaced the diaphragm upwards, have not perforated it; while the fact that in some cases the cavity has burst into the thorax renders still more confusing the use of a term which seems to imply that in all cases there is a communication exists. The meaning of the term "pyopneumothorax" is so definite and so well known that it must not be to be applied to a cavity which has usually no communication with the pleura.

THE CROONIAN LECTURES.

CONTRIBUTION TO THE HISTORY OF THE RESPIRATION OF MAN.

Delivered before the Royal College of Physicians of London.

By W. MARCET, M.D., F.R.S.

LECTURE IV.

MR. PRESIDENT AND GENTLEMEN.—So far we have dealt with the phenomena of respiration as carried on in the ordinary course of life. I now wish to draw your attention to breathing under circumstances which are not of daily occurrence; the first of these being under the influence of diminished atmospheric pressure as met with on ascending into high altitudes. This subject is important not only physiologically, but also with reference to the modern treatment of phthisis.

It must be clearly understood that the carbonic acid expired is unconnected with the consumption of the oxygen taken in the previous inspiration, as the oxygen derived from the air is carried into the circulation by the hæmoglobin, and there serves the purpose of heat production and metabolism; the carbonic acid produced in the tissues passes out into the blood, and is ejected with the expired air. Thus it is impossible to tell when a certain volume of oxygen taken into the blood may reappear as CO_2 . This point I wish to establish clearly, as I believe an objection to my work has been made on that score.

If experiments on the respiration of man could be continued for a length of time—say the whole day—then the volume of air breathed would certainly compare with the weight (or volume) of CO_2 produced; but it is not possible to do this, and the only alternative is to repeat the experiment as often as possible throughout the day, and take the means of the volume of air breathed and CO_2 produced—a method invariably adopted in my experiments. I do not claim a relationship between the oxygen inspired and the carbonic acid expired immediately afterwards, but I claim a relationship between the mean volume of air breathed and the mean weight of CO_2 expired in the course of one day.

On ascending a mountain the air pressure diminishes and the pulmonary ventilation increases, in order to aerate the blood to its full extent. Now, although the volume of air breathed increases on rising above the sea level, still the weight of that air falls; in other words, its volume reduced to dryness, freezing point, and seaside pressure diminishes. Hence it may be said that as one ascends, a less weight or volume (reduced to dryness and standard temperature and pressure) of air is breathed for the production of a given amount of carbonic acid. For instance, if at the seaside a person inspires a mean of 4.5 litres of air and expires 0.375 g. of carbonic acid per minute, or, what is the same thing, inspires 12 litres of air corresponding to the emission of 1 g. of carbonic acid, on rising to such a height that the atmospheric pressure falls by one-fourth its amount at the sea level, the volume of air breathed corresponding to 1 g. of carbonic acid, will not exceed the original 12 litres by one-fourth, and thus become 15 litres, but will be less than 15 litres.

It must be understood that the volumes of air breathed (reduced) decrease at increasing altitudes, a fact first published by a Swiss gentleman, Dr. Mermod, in 1873, and which I confirmed a few months later by observations made at much greater altitudes, his experiments being unknown to me at the time.

A number of experiments made on the Peak of Teneriffe have also shown me conclusively that in perfect health the amount of carbonic acid expired remains unaltered with increasing altitudes, at any rate, up to about 12,000 feet. According to Mermod, on the other hand, it becomes greater on rising above the sea level. On this point we therefore disagree.

Disarding for a moment the idea of the influence of altitudes, it is well known that when the temperature of the atmosphere falls, a greater volume of air is breathed and more carbonic acid expired, but the volume of air breathed

for the emission of a certain weight or volume of carbonic acid is proportionately less, hence it appears that a fall of the atmospheric temperature gives rise to the same kind of effect on respiration as increasing altitudes without change of temperature. My earliest experiments made on the Alps were all attended with a fall of temperature at increasing altitudes, this circumstance necessarily producing an increased combustion in the body in order to overcome the action of the cold; it was therefore impossible by this means to determine the exclusive influence of atmospheric pressure on respiration, hence the necessity of selecting for these experiments a mountain of sufficient height near the tropics where one might expect to find the temperatures fairly equal at different altitudes. With this object in view I spent three weeks on the Peak of Teneriffe in the summer of 1878, selecting for this inquiry four stations varying in altitude. The temperatures differed but very slightly at the four stations, though somewhat higher at the lowest, but there was no cause for any marked influence of temperature on the formation of carbonic acid.

The air was expired into an india-rubber bag of known capacity, and a sample of the air was shaken with baryta water in a glass cylinder. The fluid, having absorbed all the carbonic acid, was afterwards collected in bottles, one for each analysis, and carefully stoppered, the final analysis being made at a subsequent period.

In the following results every figure is the mean of the number of experiments entered in parentheses, the table showing the number of litres of air expired (reduced to dryness, freezing point, and seaside pressure) for 1 g. of carbonic acid expired:

	Litres	Temp.	
Seaside	12.0	75.7°	(30)
Gusfara (7,000 feet)	11.5	69.5°	(31)
Alta Vista (10,700 feet)	10.4	64.0°	(30)
Foot of terminal cone (11,700 feet)	10.3	64.0°	(5)

The difference is not great, still for 10,700 feet it amounts to 1.6 litre, hence one eighth less air was required at the two higher stations to produce through the respiration the same amount of carbonic acid as at the seaside. In other experiments made on the Col du Goant the reduction for an increased altitude of 9,800 feet amounted to about one-fifth in my own case, and rather more than one-twelfth for a young companion. On other occasions at various altitudes, from 5,115 ft. to 13,680 ft., the mean height, 11,250 ft., gave a mean reduction of 2.03 litres of air breathed for 1 g. of carbonic acid produced. These experiments show clearly that the aeration of the blood takes place more readily under diminished pressures than at the seaside, which is not easily accounted for. Paul Bert observed that the blood of various animals forwarded to Paris from the town of Mexico situated at an elevation of 7,480 feet had the power of absorbing considerably more oxygen than the blood of similar animals kept in Paris, and he concluded that the Mexican blood contained more hæmoglobin. This may be correct, but such a character could only be acquired after a number of years, perhaps of generations, while in my experiments the effect was produced, if not immediately, certainly after a few hours, when no change in the constitution of the blood could possibly have taken place.

Frankland found that candles burn more brightly in air partially exhausted by an air pump than in the surrounding atmosphere, and concluded from this experiment that the molecules of oxygen have a greater mobility in the rarefied air. The more ready passage of oxygen into the blood at the lungs on reaching a high altitude may be due to a similar cause, but I cannot think that it is in any way connected with an increase of hæmoglobin.

As regards the medical aspect of the question, with reference to the treatment of phthisis in high winter stations, as Davos and St. Moritz, people residing there must live under circumstances facilitating the aeration of their blood, and I have no

doubt that this is a primary and important cause of the beneficial effects produced. The extreme cold experienced must also be beneficial, since cold reduces the volume of air that has to be inspired for the production of a given amount of carbonic acid, so that both altitude and cold join in facilitating the respiratory phenomena.

There is another experiment of Dr. Frankland which throws light on the circumstance that cold is so little felt on high winter stations. He found that if a platinum wire carried through an air pump receiver was made red hot by an electric current, it rose to white heat when the air pressure was reduced in the receiver, although the source of heat remained unchanged, from which he concluded that rarefied air removed less heat by conduction than the same air under atmospheric pressure. In accordance with this observation Frankland accounts for the fact that cold is felt less than might have been expected in the still air of Davos, from the circumstance that the lightness of the air checks the removal of heat from the body by atmospheric conduction.

This view gains support from the statement of Paul Bert, in his book on barometric pressures, that compressed air has a tendency to produce a sensation of cold, although the temperature of the compressed air chamber may be higher than that of the external air, and with persons subject to the impression of cold this effect of increased air pressure is observed to become greater the longer the exposure and the higher the pressure. I, therefore, cannot help believing with Frankland that increased lightness of the air, acting inversely to increased pressures, assists in accounting for the remarkable fact that patients at Davos are so little troubled by the intense cold.

An easy respiration at great altitudes is in a great measure the result of training; thus while practised climbers easily ascend Mont Blanc, 15,000 feet, after about 10,000 feet are attained, have to stop frequently for a few seconds to take breath, and often give way to fatigue or to a sleepy sensation or mountain sickness. Perhaps the most remarkable illustration of the influence of training is shown in the case of Mr. Whymper, who, having fought his way slowly and patiently to the summit of Chimborazo in spite of the suffocating effect of the low atmospheric pressure, experienced no difficulty whatever in repeating the same ascent six months later, having been engaged meanwhile in explorations at great altitudes in the Andes.

It may be remembered that in my last lecture I traced a connection between "volition" and respiration; it will now be interesting to observe the effect of low atmospheric pressure on volition. Paul Bert submitted himself to low pressures in a closed chamber. At a pressure of 17.5 inches of mercury, having attempted to whistle, he found it impossible to do so; at 17 inches he suffered from dizziness, which recurred at 16.6 inches; and at 16.4 inches he felt rather unwell, and, having counted 28 pulsations at the wrist in 20 seconds, found great difficulty in multiplying that figure by 3. These statements show that Bert experienced in a marked degree what we might call want of power to respond to volition under that low pressure. When the pressure had risen to 22.2 inches he began to recover his ability to whistle. Is not this an illustration of the action of oxygen towards promoting the power of the will?

A more remarkable illustration of the effect of a deficient supply of oxygen towards the suspension of the action of volition is found in the account given by Glaisher of his balloon ascent with Coxwell on September 5th, 1862, when, at an elevation of 29,000 feet, the balloon still rising rapidly, he lost consciousness. Allow me to extract verbatim from Glaisher's book, *Travels in the Air*:

"At 1 o'clock and 51 minutes the barometer read 10.8 inches. After this I could not see the column of mercury in the wet-bulb thermometer, nor the hands of a watch, nor the fine divisions on any instrument. I asked Mr. Coxwell to help me to read the instruments. In consequence, however, of the rotatory motion of the balloon, which had continued without ceasing since leaving the earth, the valve line had become entangled, and he had to leave the car and mount into the ring to readjust it. I then looked at the barometer, and found the reading 9½ inches, still decreasing fast, implying a height exceeding 29,000 feet. Shortly after I laid my arm upon the table possessed of its full vigour, but on

being desirous of using it, I found it powerless; it must have lost its power momentarily. On trying to move the other arm I found it powerless also. Then I tried to shake myself and succeeded, but I seemed to have no limbs. In looking at the barometer my head fell over my left shoulder. I struggled and shook my body again, but could not use my arms. Setting my head upright for an instant only, it fell on my right shoulder; then I fell backwards, my back resting against the side of the car, and my head on its edge. As in the case of the arms, so all muscular power was lost in an instant from my back and neck. In an instant intense darkness overcame me, so that the optic nerve lost power suddenly, but I was still conscious, with as active a brain as at the present moment while writing this. While powerless I heard the words 'temperature' and 'observation,' and I knew Mr. Coxwell was in the car speaking to and endeavouring to rouse me before consciousness and hearing had returned. I then heard him speak more emphatically, but could not see, speak, or move. Then the instruments became dimly visible, then Mr. Coxwell, then shortly I saw clearly, next I rose from my seat and looked around as though waking from sleep. I then drew up my legs, which had been extended, and took a pencil in my hands and began observations. It is probable that three or four minutes passed from my hearing the words 'temperature' and 'observation' till I began to observe."

The case of Mr. Glaisher is very remarkable if taken in conjunction with the fact, which I look upon as proved experimentally, at all events as far as an experiment can go for the present, that the exercise of volition requires the direct action of oxygen on the brain centre concerned. In the present instance the conception of volition was not in abeyance, as Mr. Glaisher could direct his will as he pleased, but there was no response; he wished to move his limbs and could not. Hence as far as can be concluded from the experiment of Bert and the narrative of Glaisher the conception of volition does not require oxygen, but the manifestation or response of volition cannot be carried out without it.

Another effect of rarefied air when accompanied by intense cold is that it appears to check the mental faculties, producing the sensation of drowsiness so often experienced on high mountains.

Thus far the effects of diminished pressure have been considered; those produced by increase of pressure have been the subject of many inquiries. Paul Bert assimilates the effect of an increased atmospheric pressure to the respiration of a proportional addition of oxygen at ordinary pressure; this view, however, does not take into account the cooling influence of compressed air.

From Dalton's law the solubility of gases increases proportionately with the pressures, hence under increased atmospheric pressure a little more oxygen should be absorbed by the blood, and this is found experimentally to be actually the case. There is also a slight increase of carbonic acid expired, which, according to Bert, may be observed up to about 5 atmospheres, the maximum increase occurring at about 3 atmospheres. At pressures above 5 atmospheres oxidation falls below the normal, the excess of oxygen arresting rather than exciting combustion. Quoting from Bert's book, this cessation of the oxidation of tissues from excess of oxygen takes place in all living tissues; even seeds no longer germinate when maintained under pressure. Dr. G. von Liebig, from experiments made in 1875, found that at pressures of about 40.5 inches of mercury the carbonic acid expired was increased by less than 1 per cent. These experiments correspond with others I had occasion to make, when atmospheric air was inhaled in which one-third was replaced by oxygen gas. According to the views advocated by Bert, this artificial air, containing 43 per cent of oxygen instead of 20.9 per cent, would be equal to a pressure of about 2 atmospheres. In every experiment there was a large increase of oxygen absorbed by the blood, an increase which very clearly exceeded the absorbing power of the blood corpuscles, but the carbonic acid expired was but slightly, and in some cases not at all, in excess of the normal, thus illustrating very forcibly the remark made in my first lecture, that it is not the oxygen which by offering itself to the blood and tissues promotes the tissue changes. The slight excess of carbonic acid expired when the body is subjected to

increased atmospheric pressure is probably due to the greater conducting power of compressed air, which withdraws heat from the body.

Dr. C. T. Williams, in his book on *Aërotherapeutics*, states that in certain cases of asthma decided relief was obtained by the use of the compressed air bath. I account for this favourable action of compressed air in asthma by regarding the bath as a method of training the respiration. Dr. Williams observed that a larger volume of air was breathed after the use of the bath than before. This increased pulmonary ventilation will obviously assist in aerating the blood and ridding it of its carbonic acid, the percentage of which in the expired air would, I doubt not, be found lower than normal, thus assimilating the phenomenon to one of unconscious forced breathing.

To pass on to another subject: Allow me to draw your attention to the effects of the inhalation of carbonic acid, and first of all to the phenomena observed on rebreathing one's own expired air. I made experiments by rebreathing for five minutes 35 litres of air contained in a bell jar suspended over salt water. The air was inspired through nasal cannulae connected with the roof of the receiver, and expired by the mouth into the bell jar in the usual way. At each inspiration the bell jar fell slightly, and rose at the following expiration. Little or no distress was felt during the first three or four minutes, though in the last minute a slight feeling of want of air was occasionally experienced, but this varied with different people.

Tracings of this kind of respiration show that as rebreathing continues the respiration becomes deeper and more rapid, while the direction of the tracing is not quite horizontal, but has invariably a tendency to fall; this is due to the absorption of oxygen and carbonic acid in the blood and the consequent diminution of the volume of air in the receiver. The history of the phenomenon is very simple. Oxygen is consumed from the air and partly converted into carbonic acid, while the remainder is used up in other ways. Under ordinary circumstances the carbonic acid produced is exhaled; but in this case it accumulates in the bell jar, and, being inhaled, prevents the free diffusion of the gas from the blood into the lung cavity, and therefore carbonic acid becomes retained in the blood in gradually increasing quantity. Moreover, the amount of oxygen in the air inspired falls rapidly, and this air therefore becomes less and less fit to maintain life. In my inquiries 5 persons submitted to a total of 42 experiments, each of which consisted of 4 stages. In the preliminary stage the carbonic acid was determined in normal respiration. In the second stage 35 litres of atmospheric air were rebreathed for five minutes and subsequently analysed. Immediately after rebreathing, the air expired was diverted into another bell jar, till about 35 litres had been expired, after which the air given out from the lungs was collected separately for a further period of four or five minutes, both quantities being analysed for carbonic acid.

The broad results obtained from this inquiry were as follows:

1. On rebreathing air in a closed vessel, less carbonic acid is expired in a given time than in ordinary breathing, a certain proportion remaining absorbed in the blood.
2. When fresh air is taken into the lungs immediately after rebreathing the volumes of air breathed and carbonic acid expired are greater than in ordinary breathing.
3. When after the rebreathing stage fresh air has been inspired for five or six minutes the blood has recovered its normal state of aëration, and given out the whole of the carbonic acid which had been absorbed in the rebreathing stage.

Paul Bert has shown that animals, when left to die in closed vessels, are not asphyxiated from carbonic acid, but die solely from want of air, the phenomenon being the same as if they were submitted to diminished pressures corresponding to the proportion of oxygen left in the receiver in which they were confined.

In five of the above rebreathing experiments the mean percentage of the original oxygen which had disappeared was 19.2; the pressure corresponding to this reduction of oxygen would be 24.23 inches, equal to an altitude of about 7,480 feet; such a low altitude explains the absence of any

difficulty or distress in the breathing. On one occasion rebreathing was continued till the air in the bell jar contained 13.64 per cent. of carbonic acid and only 5.53 per cent. of oxygen, this percentage of oxygen corresponding to a pressure of 7.74 inches of mercury. The person under experiment felt very giddy, and the vision was obscured by a dark mist.

It is difficult to state the limit of altitude to which man can attain, because as he rises higher he needs less and less air; the secret of attaining to very great heights is training and time. Whymper reached an altitude of 20,517 feet on the Chimborazo, and Conway to 22,600 feet on the summit of the Pioneer Peak in the Himalayas.

Returning to the consideration of the influence of carbonic acid on respiration, it is often asked to what extent this gas can be breathed with impunity in the atmosphere. The subject has been investigated, amongst others, by Professor Emmerich and Dr. von Pettenkofer, who, in company with others, shut themselves up in a small vault of the Institute of Hygiene at Munich with bottles of liquid carbonic acid. Light was emitted from candles.

The gas was allowed to escape from the bottles, and when the lights went out most of the visitors left the chamber. Emmerich and Pettenkofer remained inside, and when seized with headache and discomfort took several samples of air, and then left the vault none the worse for the experiment. The analysis of the samples gave a mean of 8 per cent. of carbonic acid, which proportion can therefore be breathed for a short time without producing any serious effects. Rabbits have, according to Professors Friedlander and Harter, withstood for more than an hour 34 per cent. of carbonic acid; and even 60 per cent. was breathed for three-quarters of an hour, after which cramp and coma set in; after being exposed for a quarter of an hour in this 60 per cent. mixture, the rabbit quickly recovered in the open air.

ASTHMA.

Having said so much on respiration, allow me to offer a few remarks on a disease which is peculiarly one of the respiratory function, that is, asthma; and first of all, as an introduction to the subject, let us analyse the phenomenon of coughing. In coughing, a long breath is taken, which is exactly like a deep or forced inspiration, in which, as I have shown, a certain amount of carbonic acid is produced for work done, the oxygen being derived from that pre-existing in the contracting muscles, while a larger volume is displaced from the blood by a purely physical process; but though forced breathing is attended with but comparatively little work, in coughing the respiration is laboured, the muscles having to strain against the closure of the pharynx and forcibly expel the air from the lungs. This results in the production of an excess of carbonic acid, hence at the end of the expiration there is an increased amount of carbonic acid in the circulation.

After the forced expiration of coughing a deep breath is taken to supply the blood with a fresh quantity of oxygen and rid it of the excess of carbonic acid produced, and this process goes on till the fit of coughing comes to an end, then deep inspirations and expirations follow till the blood is again perfectly aëred and the carbonic acid in excess completely eliminated. It therefore appears that in coughing there is a tendency to a want of oxygen and a distinct excess of carbonic acid in the blood, which are conditions met with, though in a much intensified form, in asphyxia. Now asphyxia is occasionally productive of spasms of the glottis, as seen in some cases of recovery from drowning, and might not the momentary want of air produced by a bad fit of coughing be the cause of asthma in people who are subject to it? The following observation was made by a physician who at times had severe attacks of asthma though usually in the enjoyment of good health. On February 15th last, after taking a cup of tea at 2.30 A.M., loud wheezing and tightness of the chest came on, when a succession of forced inspirations had the immediate effect of arresting both the wheezing and tightness; a second attack the same night was averted in a similar manner. In this case the forced breathing returned to the blood the oxygen it was clearly in want of, while at the same time removing the carbonic acid.

I have shown in my third lecture that forced breathing is a means of supplying the centre of respiration with oxygen towards the respiratory phenomena; hence it appears to

follow that a deficient supply of oxygen to the respiratory centres has also something to do with asthma. In keeping with these remarks, it may be said that all circumstances productive of an excess of carbonic acid in the body and therefore of a deficiency of oxygen predispose to asthma. Cold and certain kinds of exercise do so pre-eminently, so does the ingestion of food, as happened in the case referred to above, where an attack of asthmatic cough came on pretty regularly two hours after dinner or at the time of the maximum production of carbonic acid from the meal.

A bad attack of asthma usually sets in with a sudden loud dry cough, coming on in the evening or at night; then follows a bronchial spasm during inspiration and the acute feeling of suffocation. After fighting for breath for ten, twenty, and in some cases thirty hours the respiratory muscles become very tired, and also volition towards the respiratory effort. Moreover, the impediment to breathing prevents oxygen reaching the centres of respiration to promote the exercise of volition for forced breathing; hence the power of the will becomes less and less.

It is difficult to reconcile the fact that some asthmatic persons find themselves better under lower atmospheric pressures, while others, on the contrary, suffer the moment they leave the sea level. This is apparently due to the circumstance that some persons take in oxygen more readily under low pressures, and others under high pressures. I cannot help comparing asthma in those who suffer under low pressures to a sort of mountain sickness—the higher they go the worse they are, and the moment they return into the lower plains the asthma passes off as by magic. If mountain sickness can be prevented by training for the exercise of climbing under low pressure, why should not asthma also yield to the training of the respiration, carried out by practising the respiratory movements wanted to carry the tidal air through the lungs to oxidise the blood and emit the carbonic acid, while imparting to the circulation a better tendency to work in perfect harmony with the respiratory requirements?

Of all means of training the respiration I think cycling is the best. When a person first takes to cycling he is troubled with shortness of breath, his heart beats uncomfortably, and his legs get tired, but after some training these discomforts all disappear. Why should not people liable to attacks of asthma also train their respiration by such a kind of exercise, of course on condition of the heart and lungs being in perfect health?

Cycling exercise first of all increases the depth of breathing, and that without fatigue, as the respiratory movements are automatic; at the same time it will accustom the rider instinctively to take in at each respiration the volume of air required to aerate the blood and to eliminate a fixed proportion of carbonic acid leaving in the circulation the precise amount compatible with health. In cycling, volition has also a good deal to do towards exercising the motor centres to take in the exact volume of oxygen required for that kind of work. Persons who do not care for cycling out of doors can take the same description of exercise at home by means of a dummy cycle.

My experience of the results of this treatment is unfortunately limited to one person; in which case it has proved eminently successful. This person took to bicycle riding three years ago for pleasure and afterwards on account of his health. He observed last summer that the attacks of asthma to which he was subject had become very much fewer, having only suffered two since last October, both of these being brought on by exposure to cold. The tightness and wheezing which occurred every night have nearly entirely disappeared, his sleep, which for years had been restless and broken, has very much improved, and all this he ascribes in a great measure to the use of the bicycle.

Allow me, gentlemen, to summarise shortly the Croonian lectures for the present year.

In the first lecture the oxygen of the atmosphere was shown to be the main agent of life, and Hermann's discovery that oxygen is an integral part of the tissues was appealed to with the object of explaining the remarkable tenacity of life of certain organisms—such as seeds. Next came an attempt to explain that it is not the oxygen of the air which, by offering itself to the tissues, produces the phenomena

of metabolism, but that the living tissues call upon the oxygen to effect the changes they undergo. The influence of tissues as the prime movers in the matter was shown by the action of cold, which, through the nervous system, first increases their vitality and consequently their demand for oxygen, though when the cold is excessive it exerts an influence the reverse in its character. Muscular exercise invariably tends to the production of carbonic acid in excess; and this led to some remarks on the temperature of the body while in the act of ascending. It was concluded that with some people there is a slight increase and with others a slight fall of temperature.

The second lecture was prefaced with a short allusion to past investigations on human respiration; then followed the history of the different forms of breathing, which were illustrated by tracings (reduced in size) taken directly from the person under experiment. Attention was also drawn to the interesting phenomena of the absorption of oxygen in the body independently of the formation of carbonic acid, and a number of analyses were quoted showing to what extent this absorption takes place.

The third lecture was given up entirely to the influence of volition on the respiration. It was shown that volition towards any kind of muscular exercise, including forced breathing, is attended with the absorption of oxygen in excess, and that this oxygen is necessary towards the performance of volition, and, if necessary to volition it must be taken up by the motor centres of volition. A remarkable effect on the development of muscular force by this charging of the motor centres with oxygen was shown to take place. Finally, an experiment was described in which, volition becoming tired out, the muscles refused to work; this experiment being in keeping with Mosso's discovery.

The fourth lecture was devoted first of all to an account of the influence of climbing on the respiratory changes, and on the state of the respiratory phenomena at high altitudes. Next rebreathing and air breathed under pressure were considered, and it was explained that the effect of rebreathed air was apparently due more to the want of oxygen than the absorption of carbonic acid. After a few remarks on the effects of breathing mixtures of carbonic acid and common air, the lecture was concluded with an allusion to asthma, and a method of treatment suggested by the considerations which may be looked upon as the substance of these four lectures.

CATS AND DIPHTHERIA.

By WILLIAM WILLIAMS, M.A., M.D., D.P.H. OXON.,
Medical Officer of Health to the Glamorgan County Council.

I have read with interest in the BRITISH MEDICAL JOURNAL of June 29th your remarks under the above heading, calling attention to the possible association of diphtheria in human beings and a suspicious illness amongst cats.

Some years ago, when acting as deputy and assistant to Dr. Thursfield, M.O.H., Shropshire, it was my lot to investigate a limited epidemic of diphtheria coincident with the deaths of three cats in one of the infected households.

In the month of December, 1889, a limited epidemic of diphtheria took place at and in the neighbourhood of an agricultural village in Shropshire.

Thirteen cases, one of which proved fatal, occurred amongst five families. The first case occurred on November 7th, at the house of Mrs. L. (in the village), in the form of a slight sore throat, but that it was of an infectious nature is clear from the fact that the children at this house, eight in number, all suffered more or less severely since that date, including a grown-up daughter who came home at the time, and was laid up with a sore throat a few days after.

The second case—taken ill November 28th—was that of a child of Mr. B., whose house was quite a mile distant from the village.

The third case was that of a servant girl of Mrs. R., next door to Mrs. L. (in the village), who suffered very severely from marked diphtheria, but ultimately recovered. The fourth and fifth houses to be attacked were in the same street.

At Mr. B.'s there were three cats kept. All these cats were

taken ill and died. The symptoms observed were wasting, loss of appetite, inability to swallow, cough, and expectoration. They were ill some days before the children, and when ill were carried about and nursed by them. The children's illnesses were attributed to this cause by the household. The dates of the illnesses and deaths, as nearly as could be ascertained, were as follows:

First cat: taken ill November 10th and died December 1st.
Second cat (yellow Persian): taken ill November 18th and died December 4th.

Third cat: taken ill November 25th and died December 7th.

Mr. B.'s two children were taken ill on November 26th and 27th respectively, and the one taken ill on November 27th died on December 9th, so that the illness and deaths of the cats preceded those of the children, and it appeared as if they had been connected. This was the opinion of the parents and people of the house. Mr. B.'s house was quite a mile from the village, and strict inquiry from the nurse and parents failed to elicit at first any connection. The nurse, however, was sister to Mrs. R., where the third case had occurred. She had visited her sister with Mr. B.'s children, but does not appear to have suffered from sore throat. Although at first sight the disease would appear to have originated with the cats, and the symptoms during life (above described) were such as would be anticipated if diphtheria affected the throats of the animals, this piece of evidence, showing a possible source of personal infection, renders it impossible to say whether the disease in the cats was any more than a coincidence. The first cat to die was examined by the medical attendant, who did not examine further than the throat, where he found no signs of inflammation, but a round worm of large size, which had choked the animal by blocking up the larynx.

Dr. Thurefield was of opinion that this was merely a symptomatic incident, and could be explained by the fact he had observed that during a febrile attack in human subjects the ascarides lumbricoides, doubtless rendered uncomfortable by the abnormal heat of the intestines, seek an exit by the bowel or the mouth. It is, moreover, possible that the violent efforts at coughing, obviously to clear the throat (described as a marked symptom in the cats) may have been chiefly, if not entirely, observed in this one cat. Another cat was unfortunately buried so as to be useless. The cat which died on December 7th was scoured, the symptoms of which were described as "coughing and something wrong in the throat." It was sent for examination to Dr. Klein, who reported that there was extensive disease of the lung not uncommon amongst cats.

Whether or not the illness of the children can be attributed to the cats or was merely coincident cannot be ascertained, but I consider that the incidents above related clearly show the desirability of examining the household cat or cats in every family infected with sore throat or diphtheria, and ever since it has been my custom to make careful inquiries after the cats.

The connection between infectious sore throat and diphtheria is well illustrated in the incidents of this epidemic, and I have often noticed that virulent diphtheria is very apt to occur shortly after the appearance of these ill-defined sore throats, and I am of the opinion that they are closely allied.

NOTES OF A CASE OF SEROUS EFFUSION INTO THE PLEURA TREATED BY FREE INCISION AND DRAINAGE AFTER THE FAILURE OF REPEATED TAPINGS.

By RUTHERFORD MORISON, M.B., F.R.C.S.,

Senior Assistant Surgeon, Royal Infirmary, Newcastle-on-Tyne.

DR. SAMUEL WEST'S report, in the BRITISH MEDICAL JOURNAL of April 27th, 1896, of a case of serous effusion into the pleura treated successfully by free incision after the failure of repeated tapping, and the interest his paper excited when read at the Medical Society of London, induce me to send the notes of a case very similar to his. My case occurred in 1882 and was recorded in a thesis presented by me to the University of Edinburgh, from which I have made the following extract.

E. A. L., aged 23, residing at West Hartlepool, was first seen on February 7th, 1882. The patient, a thin, pale, delicate looking little woman, was unable to lie down because of difficulty in breathing. Her feet were swollen. The temperature was 100.6° F.; the pulse was 96, when she was lying quiet, but ran up to 120 when she was disturbed. In the abdomen a large apparently multilobular ovarian tumour was discovered; and the right chest was found to be dull all over on percussion. Breath sounds, vocal resonance, and vocal fremitus were absent.

The abdominal swelling had commenced with what, from her description, was an attack of peritonitis seven months earlier, and three months afterwards her abdomen was tapped by her medical attendant to relieve difficulty in breathing. A large but unknown quantity of clear fluid was removed by the tapping with some relief, but the abdomen rapidly refilled.

On February 9th, 1882, I tapped her abdomen and obtained 4 gallons of the glairy fluid commonly found in ovarian cysts. The tapping relieved her, but dyspnoea at night was still troublesome.

On February 11th I aspirated the right pleura and withdrew the needle when 25 ounces of clear fluid had escaped. For two nights she was relieved; then the dyspnoea returned. On February 14th I aspirated again, slowly withdrawing through a small needle 4½ pints of fluid. The chest rapidly refilled, and by February 28th the dyspnoea had returned and the right chest appeared to be full again. I then decided to try if I could gain on the fluid by repeated small aspirations, and removed 1 pint of fluid. On March 2nd a second pint was aspirated; on March 6th a third pint; and on March 10th a fourth pint. On March 12th the chest seemed to be as full as ever, and the patient was steadily losing ground from fever, night sweats, the frequent tapplings, and inability to eat.

On March 14th, 1882, with the antiseptic precautions practised at that time, under the carbolic spray, and without any anæsthetic, I made a free incision into the pleural cavity in the middle axillary line, and inserted 3 inches of large-bored india-rubber drainage tube. Fluid rushed from the tube during its escape. On several occasions, fearing that so sudden an emptying of the cavity might cause serious disturbance, I restrained the flow. The patient, however, only felt relief, and made no complaint of pain or discomfort, except a weak sensation. Large antiseptic dressings (carbolic gauze) were applied, but in spite of frequent change and liberal use of gauze the dressings were continually soaked during the first five days. For the first two days the tongue was dry and the temperature 100° at night, otherwise there was no constitutional disturbance. On the sixth day after drainage the discharge suddenly ceased, and the dressing was for the first time found to be almost dry. From the sudden cessation of discharge I feared the tube might be blocked, but, on removing it, I found its lumen patent. A director passed into the pleural cavity also showed that it was empty. The percussion note at this time was tympanitic all over; there was a complete pneumothorax. The tube was introduced and retained for two days longer, when it was finally removed, as there was no discharge from it. The patient steadily gained ground for a fortnight, at the end of which there were no physical signs of any chest derangement, except slight impairment of the percussion note and some weakness of the breath sounds.

The abdominal swelling now began to be troublesome again, and a week later I performed ovariectomy. The operation was a difficult and severe one from dense adhesions to the parietes in the left lumbar region and the patient died half an hour after being put into bed. No post-mortem examination could be obtained.

REMARKS.—Before performing this operation I had seen Sir Joseph Lister open and drain knee-joints distended by fluid with success. This experience gave me confidence, and the result justified the means, for I have no little doubt as to it possible to have in the absence of a post-mortem examination that my patient's chest was well when she died. I have since always thought that an aseptic opening into the pleura was free from danger, that the proper surgical treatment of pleural effusions which resisted a moderate amount of tapping was to have them incised, drained, and dressed by a

careful surgeon; and my strong impression is that no present-day surgeon would be found unwilling to do as was done in Dr. West's case or my own.

CASES OF BILIARY COLIC CURED BY THE ADMINISTRATION OF OLIVE OIL.

By J. MICHELL CLARKE, M.A., M.D. CANTAB.,
M.R.C.P. LOND.,

Physician to the Bristol General Hospital.

THE case of hepatic colic cured by ingestion of olive oil, recorded by Dr. A. S. Gubb,¹ has led me to report very briefly three cases under my own observation, in which this treatment was followed by satisfactory results. The patients took the oil after meals with less difficulty than one would imagine. They began with a dose of $\frac{3}{4}$ j, and rapidly increased it, and I found that the first few doses were best taken floated on the surface of a bitter acid infusion. A dose of 8 grains of salicylate of soda was also given in a mild saline purgative before breakfast two or three times a week during the administration of the oil. The patients sought for the passage of a stone in the faeces, but did not detect one.

CASE I.—A man, aged 65, was seen by me in April, 1892, for a severe attack of biliary colic. He was a strong, healthy man, of temperate habits, who had never had any bad illness since the age of 22, when he had inflammation of the right lung. The attack for which I saw him came on suddenly without obvious cause, although he had suffered from acidity, flatulence, and dyspeptic pains for some months previously. The attack was not followed by jaundice. I saw him again in April, 1893, and he then said that he had returned to work in May, 1892, after the first attack, and was as well as he had ever been for ten weeks afterwards, but since then he had suffered from severe attacks of biliary colic about once in every three or four weeks; in the intervals his health was fairly good, but he had lost 30 lbs in weight during the year. The pain came on quite suddenly at any time of the day or night, without any cause. The attacks were preceded by indigestion, from which he appeared to suffer a great deal. The pain was so bad as often to necessitate morphia injections, and was accompanied by violent sickness; the whole attack lasting for six hours or longer, leaving him quite exhausted. When I saw him he was slightly jaundiced, but he stated that he had not had jaundice before, and that until the preceding two days bile had never been absent from the motions. He looked thin and anxious. The liver edge could be felt below the ribs, the gall bladder was not detected. The urine contained a quantity of bile pigment, which reacted twice to Gmelin's test. He was recommended to take olive oil twice daily, beginning with a dose of $\frac{3}{4}$ j, and increasing the dose as quickly as possible until $\frac{3}{4}$ vj to $\frac{3}{4}$ viij were taken at a time. This he did without much inconvenience, not disliking the oil, and he continued the treatment for about two months. The jaundice soon disappeared, and he had no return of the attacks from the time of taking the oil. I met him in the street recently looking hale and hearty. He said that he felt perfectly well, and had had no return of the attacks now for twelve months, and had regained his former weight.

CASE II.—A gentleman, aged 30, living in London. In September, 1888, I attended him for an attack of catarrhal jaundice, unattended with pain or with any symptoms of gall stones. I next saw him at Christmas, 1893; he was on a visit to Clifton, and had been taken suddenly ill with typical biliary colic. This first attack was not a severe one, and was not followed by jaundice; and he returned to London in a few days. During the late winter and spring of 1894 he suffered from repeated attacks of biliary colic at frequent intervals. Some of these were very severe, laying him up for several days, and leaving him exhausted by the pain and vomiting. His general health suffered, and he lost flesh. After the more severe attacks he had slight jaundice, and after all of them the urine was loaded with bile, and the faeces clay coloured. He tried various methods of treatment with-

out obtaining any permanent relief, including a month's residence at Llandrindod Wells for a course of the waters there in the early summer of 1894. After this he was a little better for a short time, but the attacks recurred as badly as ever during the months of July, August, and the first half of September. On the average he had an attack about once in every two or three weeks. During the whole time he had been careful to follow out the usual dietetic restrictions. On September 24th he applied to me for advice, and I recommended him to try the olive oil treatment. This he carried out thoroughly, beginning with a small dose and increasing it up to $\frac{3}{4}$ iv, or occasionally $\frac{3}{4}$ v, twice a day. He took the oil for from two and a-half to three months, leaving it off gradually. The result has been that from the time that he began to take the oil he has had no recurrence of the attacks, and has remained quite free from pain. The large amount of oil gave him little inconvenience, until towards the end of the treatment, when it began to excite nausea.

CASE III.—A stout woman of 40, who had had a large family, and who came to the Bristol General Hospital as an out-patient suffering from jaundice with repeatedly recurring attacks of severe biliary colic. Treatment by olive oil at once stopped the attacks. She had more difficulty in taking the oil than the other two patients, and could not manage more than $\frac{3}{4}$ iij at a dose taken twice, sometimes three times, daily. She attended as an out-patient for six weeks, and then ceased as she appeared quite well. I have not been able to obtain any subsequent information about her; but it is probable that if the attacks had recurred she would have come to the hospital again, as she was very pleased with the result of the treatment.

PERMANGANATE OF POTASSIUM AS AN ANTIDOTE FOR OPIUM POISONING.

By NATHAN RAW, M.D., ETC.,

Medical Superintendent and Pathologist Dundee Royal Infirmary.

I HAVE read in the BRITISH MEDICAL JOURNAL of June 22nd with great interest the original communication on the new antidote for opium poisoning by Dr. William Moor, of New York, and beg to record my own experience of the efficiency of the drug after careful trial in five cases of opium narcosis.

CASE I.—M. G., aged 27, admitted March 17th, 1893, had swallowed $\frac{3}{4}$ ij of laudanum. She was profoundly unconscious and evidently in the last stage of narcosis. Her stomach was at once washed out with a warm solution of Condy's fluid ($\frac{3}{4}$ ij to a pint of water) until the washings were quite colourless. She afterwards was given $\frac{3}{4}$ ij of liquor potassii permanganatis every hour for four hours. Artificial respiration was kept up for two hours in addition. She made a good recovery.

CASE II.—E. S., aged 59, was admitted on August 28th, 1894, having swallowed a large quantity of tinctura opii. She was comatose and could not be roused. The pupils were "pin point," the respirations 6 a minute. Her stomach was at once washed out with a warm solution of Condy's fluid, and $\frac{3}{4}$ ij of liquor potassii permanganatis given every hour. In a quarter of an hour she showed improvement, and in an hour she was able to speak. She recovered.

CASE III.—J. H., aged 35, a chemist, was admitted, having been found in an unconscious condition in his shop. He had evidently taken opium several hours previously, and the amount was afterwards found to be over a pint of tinctura opii. The same procedure was adopted, and in addition I was about to inject permanganate of potassium subcutaneously when he suddenly died from respiratory paralysis.

CASE IV.—C. M., aged 52, was admitted on November 16th, 1894, in a profoundly unconscious and comatose condition from opium and alcohol. Her stomach was at once washed out freely with Condy's fluid, and the effect was marvellous. In ten minutes she was answering questions, and it was thought she had recovered; but she relapsed into a comatose condition, when potassium permanganate was given in $\frac{3}{4}$ ij doses every hour for three hours. The stomach was continually washed out with the solution until the washings were quite clear. This patient made a good recovery.

¹ BRITISH MEDICAL JOURNAL, April 20th, 1894, p. 308.

CASE V.—The same patient was readmitted two weeks afterwards in the same state. She went out next day recovered.

The above cases are to my mind abundant evidence of the great value of the permanganate salts in cases of opium poisoning. I have had no opportunity of trying it in any other poison, but the procedure is so simple and harmless as to readily recommend itself in all cases of poisoning by opium or any of its alkaloids.

MEMORANDA:

MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, Etc.

DIPHTHERIA IN THE PUERPERIUM.

THE following notes may be of interest as illustrating the occurrence of the primary lesion of diphtheria upon the perineum as well as upon the umbilicus of the infant.

Mrs. R. was confined with her first child on October 17th, 1894. The application of forceps was necessary, and a slight laceration of the perineum resulted, necessitating two sutures. The following day the nurse complained of malaise and sore throat, and although nothing was visible beyond general redness of the fauces, it was deemed advisable that she should cease attendance on a lying-in woman; consequently she was sent away at once, and was lost sight of for the time being. The torn surfaces of the perineum failed to unite, and on the fourth day the stitches were removed. At this period there was no reason to entertain any suspicion of diphtheria.

The patient did fairly well until the ninth day after the confinement and the eighth day after the occurrence of the sore throat in the nurse, when she had a rigor, and the temperature registered 104° F. She complained of pain and tenderness in the region of the perineum. An adherent dirty whitish membrane was visible on the site of the laceration. On the separation of the cord on the tenth day a similar membrane formed on the umbilicus of the infant. The child pined and refused its nourishment, and was removed without my knowledge or consent to a children's hospital, where it died on November 7th. No complaint of sore throat was made, and the fauces of both mother and infant were normal in appearance. Under appropriate treatment the false membrane disappeared and the laceration healed. On December 20th, about six weeks after the appearance of the false membrane, the mother was seized with paraplegia, which kept her confined to her room for nine weeks; she ultimately recovered.

Although the presence of the Klebs-Loeffler bacillus was not demonstrated, I think there can be little doubt as to the diphtherial nature of the false membrane both in the mother and infant. Several cases of ordinary diphtheria in the house soon followed, one of which proved fatal. I heard afterwards that the sore throat of the nurse turned out to be diphtheria, and she probably was the source of infection for all the cases which occurred in the house.

Sutherland Avenue, W.

ROBERT FITZGERALD, M.D.

A CASE OF HYPERPYREXIA.

W.C., a retired farmer, aged 84 years, has always had good health, and, in spite of his advanced age, has had no medical advice for over twenty years. During the last year he had complained occasionally of difficulty in passing his water, but had had no treatment.

On April 18th, 1895, after his usual midday dinner, he went for a walk of about two miles in the neighbourhood of his house, and while out was suddenly seized with shivering and vomiting, but managed to return home without assistance. He went to bed, and the vomiting, coldness, and shivering continued, the whole body and bed being shaken; the bowels acted frequently, and the urine was copious. About 9 p.m. he began to lose the shivering and get warm, but the vomiting and retching continued, and the bowels acted repeatedly and unconsciously, the urine also being passed in the bed. Towards morning he became restless, tried to get out of

bed and toss the clothes off, but about 11 A.M. he was quieter, and could not be roused.

I saw him at 2 P.M. on April 19th. He was lying on his back in bed, paying no attention to anything, but, on being shouted at, would turn his head, open his eyes, and look at one, but made no attempt to speak or take any notice of what was said. The skin was hot and dry, the lips parched and caked. The temperature in the axilla was 110° F. The respirations were Cheyne-Stokes in character, each cycle occupying fifty seconds, the number of respirations during that time being 38, and the period of apparent non-breathing seven seconds.

There was emphysema of the lungs, but otherwise percussion and auscultation gave no abnormal signs. The pulse was 120, equal in force, but intermitted a beat in every two, three, or four beats; the heart sounds were normal but weak. This semiconscious condition continued in spite of treatment till about 1 A.M. on April 20th, when the breathing became more laboured, and finally stopped about 1.30 A.M. From the time he was in his usual good health till death was only thirty-six hours. How long the temperature of 110° F. lasted is impossible to say, as I only saw the patient once, his house being six miles distant and very out of the way. His dinner, consisting of salt pork and bread, was shared by his wife, who was not affected by it. I had had several cases of influenza and high temperature in the same district as the patient resided. Extreme pallor after death and rapid onset of decomposition pointed to great blood destruction. A post-mortem examination could not be obtained.

St. Mark's Road, W. E. W. SIMMONS, M.R.C.S., L.R.C.P.

THYROID EXTRACT IN UNIVERSAL ALOPECIA.

THIS drug was prescribed for a patient of Dr. Cathcart's, whose father had suffered from the same disease. In April he complained that he could hardly touch the hair of scalp, moustache, eyebrows, and axillae, without its coming out, and the loss of hair was very evident. Even on the legs it was readily pulled out. Alopecia was begun four months ago. After taking 5 gr. tabloids three times a day for ten weeks no further loss of hair on moustache and eyebrows was evident, and it did not readily pull out. The scalp has been shaved, so it is difficult to state what change has occurred: the shaved hair where present has hardly grown at all, but there is a good deal of downy hair. The patient was taking at the same time liquor strychnine.

Even so small an amount of success in an ailment considered incurable makes this treatment worthy of further trial.

HUGH E. BUNYON, M.D.,

Assistant Physician King's College Hospital.

ANGIOMA OF THE PHARYNX.

RECENTLY a lady, aged about 40, consulted me. She complained of a feeling of soreness in the throat and a tickling sensation, as if she were always wanting to swallow. These symptoms had been going on for four or five years, and she had always been laughed at and told it was indigestion. I examined the throat, and at once noticed a small tumour (an angioma) in the right side of the soft palate. This tumour was the size of and in appearance not unlike a blackberry, and encroached on the margin and upper border of the soft palate as well as on the uvula. I may add that the uvula was much relaxed and, with the rest of the pharynx, was considerably congested. I think this worth recording, as Dr. McBride, in his book on the *Throat, Nose, and Ear*, says that according to his experience neoplasms of the pharynx, with the exception of papillomata, are of extreme rarity. So far my patient has only allowed me to employ palliative measures, which have given considerable relief to the symptoms, and will not hear at present of any operative interference.

Pembroke, S. Wales.

ALEX. J. ANDERSON, M.B., D.M. Edin.

THE ETIOLOGY OF GOITRE.

WITH reference to Notes on the Etiology of Goitre, by Dr. Morris, in the *BRITISH MEDICAL JOURNAL* of July 8th, it may be interesting to mention another probable cause of goitre which I have met.

I was for some time in practice in a mining town in Monmouthshire, and goitre was very common. The cause

mentioned by Dr. Morris would not operate in my cases, the water being free from carbonates of lime and magnesia. Around the town, in closer proximity to the ironworks and pit heads are many rows of houses with a very defective water supply.

It used to be, and in some parts is, the duty of the women to bring the water from the wells to the houses, and they carried it on their heads in large earthenware "jacks," each holding about two gallons. It is easy to see that this would, for the time being, greatly increase the blood supply to the thyroid gland, which increase, being often repeated, would cause goitre.

Goitre is very much more common, too, among the older women of the place, and is getting less frequent, I was credibly informed, with each generation. The reason for this would seem to be that nowadays there are improved facilities for getting water, and less necessity for the women being "carriers of water."

I questioned several of my patients very closely, but could discover no cause for the goitre save the one mentioned. One girl, aged 30, whom I had frequently seen carrying water in the way mentioned, came to me with a goitre of recent development. The mode of carrying the water was in her case, too, the only discoverable cause.

ON

MEDICAL & SURGICAL PRACTICE IN THE HOSPITALS
AND ASYLUMS OF GREAT BRITAIN, IRELAND,
AND THE COLONIES.

UNIVERSITY COLLEGE HOSPITAL.

TWO CASES OF PERFORATED GASTRIC ULCER TREATED BY
OPERATION.

(For the Notes of these Cases we are indebted to Mr. DOUGLAS
DREW, F.R.C.S., Surgical Registrar.)

(Concluded from page 15.)

[CASE II.—Under the care of Mr. VICTOR HORSLEY.]

E. H., aged 30 years, a dressmaker, was admitted on March 23rd, 1895. She had been troubled with indigestion for about three years, with pain and a feeling of distension after food, but not associated with vomiting. These symptoms had been more severe for about two months before her admission to the hospital.

On March 22nd she felt quite well until after her mid-day dinner, when she complained of flatulence and a sense of distension, but was able to continue her work until 6.30 p.m., when she had tea. About half an hour after this meal she was seized with sudden and severe pain in the stomach, and vomited several times a small quantity. A medical man was called in, and the patient was put to bed, hot flannels applied, and a draught containing 2 drachms of brandy with powdered ginger and hot water to 10 ounces was given, and also a dose of castor oil. The pain continued during the night, and on the following day it was worse. She was brought to the hospital in a cab, the jolting greatly aggravating the pain. On arriving at about 7 p.m. she was suffering from shock, the face was pale and the lips blanched, and the eyes were sunken, with dark rings around them. The pulse was 132, and the temperature 102.4° in the rectum. Severe pain in the abdomen was complained of; it was found distended, and scarcely moved with respiration, the breathing being rather rapid. The distension was most marked below the umbilicus, and the abdominal wall was rigid, particularly on the right side. Tenderness was general, but chiefly below the umbilicus to the left of the middle line. The percussion note was tympanitic; no dullness was present in the flanks; and the liver dullness diminished in extent.

Dr. J. Rose Bradford saw the patient in consultation with Mr. Horsley, and the operation was performed by Mr. Horsley about twenty-six hours after the onset of severe pain. Chloroform was administered, and the abdomen was opened

in the middle line by an incision extending from below the ensiform cartilage to below the umbilicus. Gas escaped on dividing the peritoneum. The intestines presented in the lower part of the wound, and appeared healthy; the transverse colon was inflamed, and some lymph was found around it. The anterior surface of the stomach was exposed; it was red, and in places covered with thick exudate, as also was the adjacent margin of the left lobe of the liver. During the examination of the stomach a sudden discharge of about a pint of sour-smelling thin fluid, with flakes of exudate, occurred from an abscess situated on the front of the stomach towards the left. This was sponged away, and on further examination of the cardiac end, a round perforation (½ inch) was discovered, surrounded by exudate, which stripped off the stomach wall readily. In order to deal with the perforation the left side of the wound was firmly retracted, and the stomach gently drawn to the right. The edges of the opening were freshened with a knife, and five silk Lambert sutures were inserted with a curved ligated needle from above downwards; on tightening them, two cut out from the softened wall. After the row had been completed, a second row was put in in a similar manner, and buried the first stitches completely. The abdomen was flushed out with warm water, and closed by deep silk and superficial horsehair sutures. A drainage tube about 6 inches in length was placed at the upper end of the wound, and passed upwards towards the left hypochondrium.

The operation, which lasted rather more than an hour, was borne well. The pulse at its completion was rather better than at time of admission.

A few hours after the operation enemata were given to clear the bowels before resorting to nutrient injections. No satisfactory action followed; the bowels had been confined for five days. The patient passed a quiet night except for some pain and flatulence. No morphine was given and no food by the mouth. Water was used frequently to rinse the mouth, and enemata of peptone 3ss with water 3ivss were given every four hours.

Vomiting occurred several times during March 25th. The tongue was dry and brown, the temperature 101.8°, and the pulse 108. A soap and water enema with 3j of turpentine was followed by a free action of the bowel.

On March 26th (third day) the wound was dressed. A slight amount of sour smelling discharge was present. The drainage tube was shortened. There was no pain or distension of the abdomen, and the general condition was satisfactory.

On March 27th the improvement was maintained, but on March 28th (fifth day) swelling and pain around the left parotid came on during the night. The temperature was 100° and the pulse 92. The wound was dressed, the discharge had increased in amount and was very offensive; a smaller tube was inserted and daily dressings resorted to. Food was given by the mouth for the first time. It consisted of Benger's food 3ij hourly. On the following day, as no pain or sickness had occurred, the quantity was increased to 3iij hourly. The parotitis was treated with application of extract of belladonna and hot fomentations.

March 31st. The parotitis was decreasing, the temperature remained elevated (99.4° to 100.6°), the pulse was 94. The discharge remained about the same, but was less offensive. The quantity of Benger's food was increased to 3ij two-hourly, but some flatulence was complained of, and the quantity was therefore slightly reduced.

On April 3rd (eleventh day) the swelling of the parotid had completely subsided; the silk sutures were removed.

On April 4th the patient became much worse, the temperature rose to 102°, the respirations to 32, and the pulse to 124. Signs of pneumonia were discovered at the left base.

On April 6th the condition was less favourable, the pneumonia had extended. Skodaic resonance was well marked at the left apex. Oxygen inhalations were given every four hours; the same evening the temperature rose to 103.2°, and the respirations became much more rapid. The next morning (fifteenth day) signs of pneumonia had developed at the right base, cyanosis came on, and the patient gradually sank.

Necropsy.—The lower part of the wound was firmly united; above this the union was not so firm, and for a space of 1 inch had gaped open and a small protrusion of the large in-

testine, $\frac{1}{2}$ inch in diameter, had occurred; this was due to a moderate degree of distension which came on a few hours before death. At the upper end was the sinus of the drainage tube; on opening the abdomen the intestines were slightly adherent along the scar. There was no general peritonitis present. The sinus of the drainage tube led into a cavity containing fetid pus; it was bounded in front by the abdominal wall, above by the left lobe of the liver; on the left side the wall was formed by the diaphragm and spleen, and behind lay the stomach with the small omentum. At about the centre of this part of the wall of the stomach was seen the perforation; it was gaping open, the sutures had all cut through, and were lying on the right side of the opening, which latter measured about $\frac{1}{2}$ inch, and was situated near the small curvature towards the cardiac end. This abscess had extended backwards round the liver, and opened through an aperture in the diaphragm into the base of the left lung. Other abscesses were found; a small one between the liver and the diaphragm on the left of the falciform ligament, and another larger, containing about 3 ounces of offensive pus beneath the right lobe of the liver. A second ulcer was found on the posterior surface of the stomach, 2 inches to the right of the larger one, and also situated near the smaller curvature. The stomach at this spot was adherent to the peritoneum, covering the pancreas by recent adhesions, and on separating these a small perforation was discovered. On opening the stomach the mucous membrane was red and somewhat thickened around the ulcers, the edges of which were sharp. The remaining mucous membrane did not present any abnormal signs. The contents of the stomach were a thin, brown, offensive fluid. The colon was distended, and a small patch of redness was seen in the posterior part of the cecum (?post mortem). The left lung was adherent generally by recent lymph. There was no fluid in the pleura. The diaphragm extended as high as the anterior end of the fourth rib on the left side. The base of the lung was firmly adherent to it, and on separating it the abscess communicating with the lung was opened; it measured $1\frac{1}{2}$ inch in diameter, and extended into the lung about 1 inch, the cavity being irregular, sloughy, and very offensive. The lower lobe of the lung was small, and was nearly solid with pneumonia having a lobular distribution; the upper lobe was also very extensively affected with pneumonia. The right pleura and lung presented similar appearances, but not in such an advanced degree. The heart was normal. There was an excess of serous fluid in the pericardium. The kidneys were rather dark coloured, but otherwise normal. The capsule of the liver was thickened where it formed the wall of the abscesses; nothing abnormal was detected on cutting into it. The left lobe extended to within 2 inches of the left side of the chest.

REMARKS BY MR. HORSLEY.—The unfavourable termination of this case was a source of the deepest regret, inasmuch as the progress having been so remarkably good during the first twelve days, and the operation naturally not revealing the retrogastric misadventure, the patient's recovery seemed well assured. In a parallel case where so long a period elapsed from the time of perforation, it would seem advisable not only to make even a more extensive cleansing and breaking down of adhesions than was carried out, but in addition to examine as a routine measure the posterior aspect of the stomach, or at least its relations to the surrounding viscera, and, above all, to the diaphragm. So many cases have now been recorded of spread of the infection through the diaphragm that attention was specially directed to the possibility of this occurring, and long before the first physical signs in the left lung arose, but the development of the infection was sudden and rapidly fatal.

THE summer session of Anderson's College Medical School, Glasgow, which closed last week, has, we learn, been the most successful in its history. Upwards of 175 students were in attendance, which is a number in advance of any previous year.

DR. ELLIOTSON, of Stoke Hall, Ipswich, has been added to the Commission of the Peace for the county of Suffolk.—Dr. R. D. EVANS, surgeon to the Oakley Hospital and Festiniog Slate Quarries, has been placed on the Commission of the Peace for Merionethshire.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

F. H. CHAMPNEYS, M.A., M.D., President, in the Chair.

Wednesday, July 3rd, 1895.

SPECIMENS.

THE following specimens were shown:—MR. DORAN (for Mr. BRADBURY and Dr. LOWE): A Monster, *Acardiacus Paracephalus*.—DR. BLACKER: Uterus affected with Fibroids and Carcinoma of the Cervix, obtained 8 years after Oophorectomy.—MR. TARGETT: (1) Abscess in Ovary caused by direct infection through connective tissue; and (2) Casts of Vaginal Mucous Membrane.—DR. AMAND ROUTH: Macerated Skull of an Anencephalic Fetus. Dr. Cullingworth: Pedunculated Fibro-myoma of the Broad Ligament with Twisted Pedicle.—DR. PLAYFAIR: Tubal Abortion.—DR. GALABIN: (1) An improved form of "Sanitary Towel"; and (2) Pregnancy in a Rudimentary Uterine Horn.

DEVELOPMENT OF THE HUMAN PLACENTA: ADJOURNED DISCUSSION.

DR. DARIN asked Dr. Eden how the specimens of placenta and decidua from which the sections were made had been obtained and prepared, so as to exclude the possibility of the hæmorrhages into the decidua in the earlier stages being artificially produced. It was highly probable that the hæmorrhages were normal, for the process thus resembled that of the formation of the menstrual decidua, which was another example of intense activity of function. The resemblance was interesting as bearing on the connection of ovulation with menstruation. Hæmorrhages as part of an early stage in the formation of the placenta were known from the observations of Hübner and others to take place in the trophoblast of some of the lower animals, where cleavage occurred in this part of the chorion, and produced spaces which became filled with maternal blood. Dr. Eden had said that what had been described as multinucleated cells by many observers were practically always sections of buds of the chorionic villi lying in the sinuses. These cells had, however, been demonstrated in the sinuses of the uterus itself, and more deeply than the villi were likely to penetrate, and had been described by Helme as collecting around the vessels in the uterine wall towards the end of pregnancy in connection with the hyaline degeneration of the sinus epithelium which took place then. This change had been first described by Friedländer, and, in the Society's *Transactions*, by John Williams, vol. xx, p. 172.

REMARKS were made by Dr. GRIFFITH and Dr. GALABIN.

DR. EDEN, in reply, said that the specimens of early ova shown at the last meeting might fairly be regarded as healthy; they were examples of abortion occurring from accidental causes, not from intrauterine disease. In answer to Dr. Galabin, he said that the maternal vessels became to a great extent opened up by the destructive action of the trophoblastic buds, and this process was the principal factor in the development of the circulation through the intervillous spaces. Similar changes had been described in the development of the placenta of many other animals besides man. The question of fibrinous and calcareous degeneration in the placenta he hoped to discuss in a subsequent paper.

PLACENTAL POLYPUS.

MR. DORAN read this paper. In examining the clots from tubes which he had recently removed in cases of suspected tubal gestation, he compared the clots with sections of true placenta, and of retained placental fragments. He also examined, for the second time, sections from a polypoid growth found in the uterus of a woman aged 39, who died many years ago after the removal of a cystic kidney by Sir Spencer Wells. There had been no hæmorrhages; in fact, the patient believed that she was pregnant on account of the absence, for several months, of menstruation. The uterus, with the polypus attached to its wall, and the ovaries showing a large corpus luteum on one side, are preserved in the Museum of the College of Surgeons (No. 4,522, Pathological Series). In 1877 Mr. Doran believed that the polypus was a convoluted anghema. Dr. Boldt had quite recently detected a

tumour of that kind in the uterus. The College specimen, however, proved on careful examination to be made up of placental tissue. It was a true placental polypus. In all other recorded cases uterine hæmorrhage was present. The author dwelt on recent opinions concerning placental polypus. According to the recent researches of Klässon of Kieff, and Lejars and Lévi, of Paris, the so-called "fibrinous polypus" was only a form of placental polypus, if not identical, the placental tissue having been overlooked. The author finally referred to Hartmann and Toupet's important investigations on the results of retention of placental tissue when, instead of septic changes, organisation occurred. They found that this tissue might develop into innocent deciduoma (that is, placental polypus), hydatidiform mole, and chorion-celled sarcoma. This last growth was the "malignant deciduoma," or cancer following gestation, which had been so frequently described of late, on indisputable evidence, by Continental authorities. The author asked why, if this grave disease were so frequent in Europe, it had hitherto escaped the notice of British teachers and practitioners.

Dr. HERBERT SPENCER had six years ago met with a case which he believed to be of the nature of the deciduoma malignum of Continental authorities. A woman about 25 years of age died two months after delivery with symptoms of septicaemia and signs of uterine cancer. During life several pieces of putrid "placenta" had been removed. At the post-mortem examination growth and ulceration were found in the situation of the placental site where the wall was almost eaten through, and also (unlike most cases) in the cervix. The microscopic examination of the uterine growth was somewhat unsatisfactory, but it appeared to be sarcomatous. In the lungs were many secondary growths, some as large as a walnut; under the microscope they were evidently sarcomatous. He had hoped to meet with another case in which the microscopic examination of the primary growth would be more satisfactory; but as the above-mentioned appeared to be the only case of the kind in this country he would be happy to bring it before the Society. The specimens were in University College Museum.

Remarks were also made by Dr. GALABIN and Dr. GRIFFITH. In reply to Dr. Galabin Mr. ALBAN DORAN said that hydatidiform moles undoubtedly displayed malignant characters in certain cases. They were myxomatous, but it must be remembered that general pathologists were not all agreed as to the limits of the term "myxoma." Sometimes mucoid tissue was normal and not in any sense a new growth; sometimes it was clearly associated with sarcoma. Dr. Griffith's tumour seemed to be a true fibrinous polypus, as no placental tissue was detected in its substance. Dr. Herbert Spencer's case was of the highest interest; it appeared to be the first instance of malignant deciduoma in the British Isles. In conclusion Mr. Doran recommended careful inspection of all specimens of malignant disease of the uterus from patients under 40 already preserved in museums. In future in any patient of this kind, close inquiry should be made as to the occurrence of abortion within a few years of the appearance of evidence of malignancy.

REGISTRATION OF MIDWIVES.

The report of the proceedings at the June meeting of the Society omitted to state that the President announced that the General Medical Council had approved of a form of certificate to be given to candidates successful at the Society's examinations in midwifery. Copies of the form were handed round.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

E. A. BROWNE, F.R.C.S. Edin., Vice-President, in the Chair.

Friday, July 5th, 1895.

THE ASSOCIATION OF CERTAIN FORMS OF MYOPIA WITH DISEASE OF THE NOSE AND PHARYNX.

This paper was read by Dr. BATTEN. After referring to a former paper read before the Society in July, 1893, in which he held that certain constitutional diseases produced myopias distinguishable and differing from each other according to their cause, he proceeded to describe a special form of myopic

fundus which he associated with certain diseases of the nose and pharynx. The chief characteristics of this form of myopia were (1) the existence of localised posterior staphylomata at, or in the immediate neighbourhood of, the optic disc, or in the nasal side of the fundus; (2) the tilting of the optic disc in the direction of the staphyloma; (3) the oedematous condition of the more prominent margin of the optic disc. This oedema, or "pseudo-neuritis" he considered to be secondary to and caused by the tilting of the disc. The conditions of the nose and throat with which he associated this form of fundus were adenoid vegetations, enlarged tonsils, deviation of the septum, blows on the nose and forehead, cœdema, syphilitic disease of the nasal bones, and chronic otorrhœa. He quoted cases in which myopia had immediately followed the onset of some of these conditions, and in conclusion said that the presence of the oedema was generally a sign that the cause was still in active operation; that the visual acuity was seldom good in these cases, even when the degree of myopia was low, and was especially bad when the staphyloma was to the nasal side of the optic disc; that the whole condition was one indicative of a progressive myopia, and that the oedema and tilting both tended to disappear with the progress of the myopia.

The CHAIRMAN thought more evidence than was present in Dr. Batten's paper was necessary to convince those who had not specially studied the subject. Many factors, like previous attacks of scarlet fever, rheumatism, or rheumatic fever, would have to be eliminated. All these, as well as other exhausting diseases, were known to be sometimes followed by the production or increase of myopia.

Mr. SPENCER WATSON thought it a pity that nothing had been put forward by Dr. Batten to explain the relationship between the cases of nasal disease and myopia; he had looked for some information as to the constitutional cause at the root of these affections. He had seen interstitial keratitis of syphilitic nature in which myopia had developed, and he regarded this as due to the softening of the whole eye by the disease, leading to its expansion. This would explain the association between the myopia and some diseases of the nose having a similar constitutional origin.

In reply, Dr. BATTEN said he had dealt with the constitutional causes in his previous paper; he had only brought forward some evidence in the present one. There was a close connection between the sphenoidal cells and fissures and the blood supply to the eye; in a measure the eye was to be regarded as an end organ, and interference with its blood supply was likely to lead to changes analogous to that produced in clubbed fingers.

INDIAN OCULIST'S INSTRUMENTS.

Mr. ADAMS FROST showed a complete set of Indian oculist's instruments which had been presented to the Society by Surgeon-Captain Drake-Brockman, and described the method of operating. There was no attempt at asepsis or ordinary cleanliness; the lower lid was everted, an incision made in the ciliary region with a lancet, and the lens was couched by passing an instrument through the incision. Most eyes were lost by panophthalmitis or secondary glaucoma.

Surgeon-Colonel DRAKE-BROCKMAN commented on the difficulty of obtaining these instruments; they were handed down from father to son for generations. Fewer than 10 per cent. of the cases could be considered successful cures.

CARD SPECIMENS.

The following were shown:—Mr. E. H. CARTWRIGHT: Modification of Thomas's Arrangement of Holmgren's Woods.—Mr. FISCHER: Symmetrical Ulcers of Both Corneas.—Mr. D. MARSHALL: Double Enophthalmos.

ELECTION OF OFFICERS.

The following were elected office-bearers and members of Council for the session 1895-96:—President: *E. Nettleship. Vice-Presidents: Stephen Mackenzie, M.D., Henry Power, Edgar A. Browne (Liverpool), Thomas Barlow, M.D., G. Anderson Critchett, J. B. Story (Dublin), *John Cooper, *G. A. Berry, M.D. (Edinburgh). Treasurer: George Cowell. Secretaries: Samuel Herbert Habershon, M.D., *John Bowring Lawford. Librarian: W. Adams Frost. Other Members of Council: M. A. Adams (Maidstone), Charles E. Beevor, M.D.,

*T. H. Bickerton (Liverpool), Ernest Clarke, M.D., *A. Deas Davidson, M.D. (Swansea), *E. F. Drake-Brockman, A. Hill Griffith, M.D. (Manchester), *Gustavus Hartridge, Joseph Nelson, M.D. (Belfast), *D. Argyll Robertson, M.D. (Edinburgh), A. E. Sanson, M.D., *James Taylor, M.D. *Honorary Member of the Society*, J. S. Bristowe, M.D., F.R.S. The gentlemen whose names are marked with an asterisk (*) were not in the Council, or did not hold the same office, during the preceding year.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

T. S. CLOUSTON, M.D., President, in the Chair.

Wednesday, July 3rd, 1895.

CASES.

MR. W. ALLAN JAMIESON showed (1) A child suffering from Hydrum Vacciniforme (Hutchinson's Summer Rash) on the face, ears, back of hands and wrists. The condition was worse in summer, but not absent in winter. It had been treated by salicylic acid in resorcin, plus brown pigment so as to exclude the irritating rays of the sun; (2) A case of Ichthyosis in a patient aged 34.—Dr. NORMAN WALKER showed a little boy suffering from Pityriasis Roseola.—Dr. JAMES showed a boy who three years ago when in a swing had got a blow on the head, a fracture (depressed), fragments of bone had been removed, and he had then been eight months in the infirmary. Last Christmas an epileptic fit occurred. Since then there had been several, but there had been no local manifestations, and no aura. He was trephined. Now he was brought to show the pulsations in the brain, and apparently a height of 4 ft. of water in this case was equal to the pressure in the vessels of the brain. Very slight mental effort evidently meant an increase of blood pressure in the brain.

SPECIMENS.

Dr. EDWARD CARMICHAEL showed a Sarcoma of the Jaw.—Dr. R. F. O. LEITH showed (1) a specimen illustrating Rupture of the Pancreas and Duodenum at the Duodeno-jejunal Junction caused by the kick of a horse; only nine such cases had been recorded so far as he knew; (2) Rupture of the Liver in a vanman who had been in a collision, and who died of collapse from shock and internal hemorrhage; (3) Rupture of Kidney caused by a falling tree; (4) Multiple Tuberculous Tumours in the Cerebellum, Chronic Hydrocephalus in the Brain (specimens and photograph); (5) Perforative Appendicitis, with Subcecal Abscess, and resulting gangrenous abscess in the abdominal wall, thigh, and vulva (specimens and photograph).—Mr. A. G. MILLER showed an Abscess in the Temporo-sphenoidal Lobe, the result of middle-ear disease. There had been practically no symptoms till quite late.

THE TREATMENT OF FRACTURES NEAR A JOINT, AIDED BY MASSAGE AND MOVEMENT.

Mr. A. G. MILLER read this paper. Arbuthnot Lane had expressed the opinion that the present treatment of such cases was not satisfactory, and Marmaduke Pott had said that as soon as the bones had united the limb was put up in a stiff case, leading to atrophy, etc., and had recommended that the fracture should not be set till after seven days or so after the injury; stiffness, swelling, and long time for treatment, seemed to be the main defects of present treatment. By way of illustration, Mr. Miller took first Colles's fracture, in which resulting stiffness was so common. The best results were got when only movement was employed and perhaps still better when there had been no treatment at all. Secondly, Pott's fracture. The points were, damage to bone, ligament, synovial membrane, and extravasation of blood. After six weeks' treatment the usual result was a stiff ankle joint and uselessness for work. It was too often the case that the fracture was treated, and the damaged joint ignored. Ununited fractures were rare, ankylosis much more common. Rest alone did not cause ankylosis, the injury alone did not; but the long continued rest was the main cause. Fractures were taken down several times without harm. But why not attempt? He believed massage led to more rapid union of fractures, prevented adhesions, and saved time. Passive movement of course was meant. Mr. Miller illustrated his remarks by showing a young man with a compound fracture

below the knee, which had been treated according to the principles here laid down, and the result was excellent.

Dr. JOSEPH BELL said there were some fractures that did not do well however carefully they were treated. He used splints for a very short time in fractures near the elbow, none at all in Colles's fracture, and in Pott's full and free massage. In sprains he believed massage ought to be given very early.

Dr. J. H. A. LAING in sprain began massage when the swelling had gone down, on the third day or so passive movement, and usually walking was possible in a week. Fracture near a joint healed better and faster with careful massage. There was no necessity for moving the fracture itself.

Mr. ALEXIS THOMPSON thought that in cases of comminuted fracture near the elbow-joint the best way was to cut down and fix the fragments. Splints in such cases were not of much use.

Mr. STILES said we were advised to begin massage 24 or 48 hours after the injury. But what were we to do during this period? How were we to get rid of the effused blood? Probably plenty of cotton wool and domestic bandage best aided this. The wool should be put not merely on the joint but above and below it.

Mr. A. G. MILLER replied.

RUPTURE OF THE PANCREAS.

Dr. R. F. O. LEITH read a paper on Ruptures of the Pancreas: their relation to Pancreatic Cysts, with some remarks on Treatment. Cases following upon severe injuries and proving quickly fatal, in which the pancreas was found to be ruptured, were first spoken of. The author gave particulars of 2 new cases, one in a boy of 4 years, and the other in a young man, and then referred to 7 other cases previously published. In all of these except two some other viscera had suffered at the same time, and the cause of death (internal hemorrhage) was referable to that rather than to injury of the pancreas. No one sign or symptom had pointed to this gland in particular, and a definite diagnosis was possible only after exploratory laparotomy. He explained how the gland and its covering peritoneum could be thoroughly explored by means of a Ferguson's speculum and an electric lamp. Hemorrhage from the gland itself was comparatively slight, and could easily be controlled by pressure or by ligation of the divided ends as recommended by Senn. Suturing of the peritoneal covering alone (either continuous or interrupted) brought the ends of the gland into close approximation. He next referred to non fatal injuries implicating this gland, and their relation to the so-called "traumatic pancreatic cysts." He gave a table of 16 published cases of this kind, indicating that, while there was little or no doubt that the cyst had been caused by the injury, there was considerable room for doubt that that injury had been one of the pancreas. In investigating this question he said that, as post-mortem evidence was so scanty, we were compelled to argue from analogy, after considering all the possibilities. Cysts, both traumatic and spontaneous, had been met with in the peritoneum at a distance from the pancreas. These were sometimes hemorrhagic and sometimes serous, and as they could occur elsewhere they might readily enough take their origin in the lesser omentum, and come to simulate true pancreatic cysts. He discussed the possibilities of spontaneous hemorrhage from the pancreas and suprarenals, and the mode of action of such in the production of cysts. Other fallacies might arise in connection with cysts of the suprarenals, kidney, spleen, or even liver. It was, therefore, necessary to be careful in calling any mesogastrie cyst pancreatic; chemical and microscopical examination might help, but failed to do so in many cases. As regards treatment, he objected to aspiration with or without the injection of saline, and to the excision of the cyst, as both being dangerous. Antiseptic incision, with drainage, was the favorite method, and, while not universally successful, it had given very good results. It was, however, open to the obvious objections of interfering with the usefulness of the anterior abdominal wall, of imperfect and slow drainage, of the possibility of a permanent pancreatic fistula remaining, or even leading to malignant disease. He therefore thought that in all cases, particularly the broad scissile ones that did not reach the abdominal wall in front, had better primarily be

attacked from behind. From many observations on the cadaver he showed how this could be done by means of a vertical incision at the outer border of the left rectus, beginning at the twelfth rib. The posterior surface of the kidney and the renal vessels were easily defined, and the cyst could be easily reached by the exploring finger working inwards and slightly upwards from these vessels. In old-standing cases the cyst might even extend lower than these vessels, and could be opened below them. He anticipated that this method would be followed by much more speedy cure.

Dr. JOSEPH BELL made some remarks on his experience of pancreatic cysts.

ALCOHOLISM AND ITS EFFECTS.

Dr. LOCKHART GILLESPIE read a paper entitled "Statistics concerning the Patients admitted into the Royal Infirmary suffering from Alcoholism and its Effects during the last Five Years." During that period 1,284 patients had been admitted (only those were reckoned who were suffering from alcohol and its immediate effects), 935 males and 329 females. In this number there had been 44 deaths, 38 males (4 per cent.), and 6 females (1.8 per cent.). As to monthly admissions these were most in January; there was a slight rise in April, a great rise in July and August, and a fall from that time till the lowest number was reached in November. There was an excess in summer, more especially in female admissions. A graphic chart of the above facts closely corresponded to a similar chart of the deaths in the eight principal towns of Scotland for the same period. As to occupation: males, 461 labourers, of which 271 were outdoor labourers and 190 indoor. The outdoor workers drank most in summer, the indoor most in winter. One hundred and nineteen shopkeepers, who appeared to drink most in summer. Professional classes, 108. These drank most in summer, and were more prone to mental disturbances other than delirium tremens. Liquor trade, 81, with 32.7 of delirium tremens, but only 2 of neuritis. Cabmen, 68, in which class drinking apparently varies with wet weather. As to females, 169 were housewives and 28 per cent. were surgical cases. Fifty-four charwomen, with 44 per cent. of surgical cases. These were the most pugnacious of any. There were 101 cases of neuritis, chiefly in summer, and none in the five Novembers of the period covered. One hundred and seventy-nine cases of delirium tremens, with excess in July. Dr. Gillespie's inference from these facts was that drinking varied with the holidays.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—At a meeting on June 26th, Dr. F. SMITH, F.R.S., President, in the chair, Dr. SHEPHERD TAYLOR showed a Hypertrophied Nail removed by Dr. Collier, of Yarmouth, from a woman's thumb. It was about 3 inches in length, and nearly straight. It had been growing for eleven years, and had originated after an accident.—Dr. EDDOWES showed a woman with considerable Hypertrophy of the Nails of both Great Toes. They were curved like a ram's horn, and had not been cut for the last twenty-five years. He suggested cauterisation of the nail bed. The President said Dr. Shepherd's specimen was the longest nail which he had seen, and compared it to a specimen in Gyp's Museum of a sebaceous horn of the neck. He considered that the origin of the trouble in the toe was an affection of the matrix. Mr. BIDWELL suggested that Dr. Eddowes's case would be best treated by the removal of the whole matrix; the edges of the wound being afterwards brought together with sutures.—Dr. EDDOWES also showed a case of Angiokeratosis which had affected the outer side of the right leg. Above this were several varicose veins; others had existed beneath the patch of keratosis, but had since become obliterated. The skin at first was exceedingly rough, but had improved under treatment with iodine and creolin, followed by the application of an Unna's gelatine dressing, which was worn for twelve weeks.—Mr. BIDWELL showed a man, aged 74, suffering from a Rodent Ulcer on the outer side of the Thigh. A portion had been removed for microscopic examination, and Dr. ABRAHAM had pronounced the growth to be typical of rodent ulcer. Dr. CROCKER suggested that the appearances were rather those of a slow-growing epithelioma. Dr. ABRAHAM insisted that the sections showed typical rodent cancer, and that the appearance of the ulcer was almost unmistakable.—

Dr. SROWERS showed a young woman suffering from an Affection of the Nails. The matrix receded from the nail, and the nail itself grew up curved and brittle. It was similar to the condition seen in eczema and psoriasis, but there was no evidence of either disease. The patient had recently suffered from severe mental and bodily strain. The President remarked that in many of these cases the disease depended upon general depression in health, and that it was more common in old than in young people. Dr. CROCKER considered that arsenic benefited most of these cases; he mentioned one in which a similar condition of the nails indicated when a patient was overworked, and after taking a holiday the condition of the nails improved. He considered the disease was more allied to eczema than to psoriasis.—Dr. ABRAHAM showed a case of Bromide Rash in a young woman, aged 26, who had been taking bromide on and off for thirteen years. The eruption had started in the scar of a bite by another woman.—Dr. ABRAHAM also showed (for Mr. TAY) a case of Prurigo in a young woman, aged 23 years. It had existed for four or five years as an eruption of large papules, which were very irritating. The condition was not like Hebra's prurigo. Dr. CROCKER objected to the term "prurigo," and considered that the case should be called urticaria, with persistent nodules. He suspected that wheals would be found if the patient were watched.—Dr. ABRAHAM also showed a case of Lupus Verrucosus affecting the Hand. In one of these the disease was now symmetrical, the patch on the right hand having appeared over thirty years after that on the left hand. At first sight the condition rather suggested syphilis, but the history was against this view.

REVIEWS.

MATERIA MEDICA, PHARMACOLOGY, AND THERAPEUTICS: INORGANIC SUBSTANCES. By C. D. P. PHILLIPS, M.D., LL.D., F.R.S. Edin. Second Edition. London: J. and A. Churchill. 1894. (Demy 8vo, pp. 912. 21s.)

THE present work is the second edition of one published under the same title in 1882, but the original has been out of print for several years. It is hardly a matter for surprise that in writing on a subject which has during the last decade made such great strides Dr. PHILLIPS has found it necessary to make many alterations and additions. This has been, in his opinion, particularly necessary in the sections devoted to oxygen, nitrous oxide, the mineral waters, certain metallic agents and their compounds, and the more recently introduced substances, such as iodoform and similar compounds. By a reduction of the size of the type employed, such additions have been made without any material increase in the bulk of the volume.

The system of classification adopted seems at first sight somewhat perplexing, and it is difficult to see what has been gained either in accuracy or in convenience by arranging the various medicinal agents discussed in an order which is admittedly based neither on a chemical nor a physiological foundation. The student of the present day is accustomed to consider drugs under one or other of these methods of arrangement, so that it is perhaps hardly advisable to discard them unless it can be shown that by so doing some very material advantage is gained. The modified alphabetical arrangement adopted by Dr. Phillips can scarcely be said to have any features likely to recommend it for adoption by others, and is at the same time somewhat perplexing to the older student or practitioner, for whom the work is evidently chiefly intended.

As regards the material presented, while a good deal of space is devoted to questions of pharmacy and materia medica, it is the therapeutic observations which will be found of the greatest value. These are largely the outcome of the author's personal experience, but when this has been but slight the works of others—chiefly English and American writers—have been freely consulted; the information given as to the clinical application of remedies will, therefore, be found to be, for the most part, complete, and sufficient for the needs of the busy practitioner, to whom the

conciseness of the author's remarks will be a distinct advantage.

Chemical information is remarkable chiefly by its absence, and it is doubtful whether the pages devoted to such matters might not have been more advantageously utilised otherwise. Such information as is given on the pharmacy of the various drugs is not of a nature to satisfy the demands of the student, and is unnecessary to the physician already brought face to face with the problems of actual treatment. Some of the statements are a trifle misleading; for instance, boroglyceride is described as a compound of "glyceryl" with boric acid, while the equation given immediately afterwards illustrates the interaction of boric acid and glycerine, which is probably not quite so simple as is there stated.

The most valuable section of the volume is that devoted to the consideration of the composition and therapeutical indications of the "mineral waters." Brief notes, sufficient in most instances, are given on this subject, and as great pains seem to have been taken to include not only the well-known spas, but also many which have not already been prominently brought to the notice of the profession, this portion of the volume will be found particularly useful to those who have neither the time nor the opportunities for consulting works specially devoted to hydrotherapeutics.

The author promises a revised version of his book on the *Organic Materia Medica* at an early date.

LEITFADEN DER GERICHTLICHEN MEDICIN. [Guide to Legal Medicine.] By Dr. K. J. SNYDEL, Professor an der Universität und der gerichtlicher Physicus in Königsberg. Berlin: S. Karger. London: Williams and Norgate. 1895. (Demy 8vo, pp. 290. M.7.)

THIS is a well-written introductory manual for the study of a somewhat difficult subject. In the preface the author deprecates any claim for the book to be regarded as a complete treatise upon medical jurisprudence, but states that he has endeavoured to focus attention upon several important subjects as to which both students and medical practitioners are but imperfectly informed. These subjects are suffocation, poisoning, causes of death in children, and *post-mortem* examinations. The articles upon these matters are thorough and well arranged. The author is evidently quite at home in the *post-mortem* room, and his instructions for the routine examination of the dead body, and the interpretation to be placed upon facts observed is perhaps the best chapter in the book. The difficulties in connection with the questions of alleged rape, still and live birth, how long a child has lived after birth, and causes of death in infants are well discussed. The chapter on deaths from poisoning and the symptoms met with during life is also well written; it is a little too short, and could have been improved by more details as to the chemical examination of the fluids found in the body after death. The book, being written for Germans, naturally deals with the legislative code of Germany and the relations of the medical man to the law of the State. This part of the book is difficult to criticise, but it appears to be well arranged. It is interesting to read that by the Imperial law anyone who inoculates or vaccinates carelessly is liable to a fine of 300 marks or three months' imprisonment, and that anyone who illegally performs those operations is liable to a fine of 150 marks or fourteen days' imprisonment. Other fines and penalties resulting from malpractice are quoted from the code of laws controlling the whole practice of medicine in Germany. Some portions of the book may be of use to English readers, but on the whole it appears to be in no way superior to several well known manuals on the same subject in our own language.

MANUAL TRAINING MADE SERVICEABLE TO THE SCHOOL. By Dr. WOLDEMAR GONTZE, Director of the Leipzig School for Teachers. Translated by W. G. FINE, M.A., lately Assistant Master in Lancing College. London: O. Newmann and Co. (Or. 8vo, pp. 157. 3s.)

THIS book consists of a graduated course of lessons in the construction of apparatus, and is a practical attempt to utilise manual training in the general interest of school work.

We learn from the two introductory chapters that the author advocates manual training because he believes it promotes the educational work of the school, and helps to train the pupils in neatness, order, and accuracy, as well as in industry. The school workshop, by intensifying the influence of writing and drawing, exercises the hand, eye, and sense of form, and deserves well of the school by cultivating a habit of close observation. The author also believes that manual training supplements school instruction by adding real experience to theoretic knowledge, and in so doing assists the development of practical intelligence; it also presents the ideas treated in the school in the form of immediate perceptions, and helps the learner to make for himself the appliances necessary for these perceptions and for experimental purposes. Manual training is not intended to qualify the trained for industrial pursuits, but to form a part of the essential education of the pupil. Exercises in cardboard work, bench work, metal work, and working in glass are fully described, and copious illustrations of the appliances used in various subjects are given. The book seems entirely to fulfil the purpose for which it was written, and the translator, we may add, has done his work well.

A SYSTEM OF LEGAL MEDICINE. By A. M. HAMILTON, M.D., and L. GODKIN, in two volumes. New York: E. B. Treat. 1895. Vol. i. (Roy. 8vo, pp. 657. 5.50dols.)

THIS is the first instalment of what promises to be a useful and standard work of reference. A large number of accomplished writers have assisted in its production, many of them men who have made their mark in the special subject of which they treat. Naturally, the articles vary a good deal in style; some are written solely from the practical standpoint, the author quoting only the cases which have occurred within his own experience; others rely mainly on the classical cases mentioned in all the leading textbooks; while others, again, have given a careful and accurate summary of all the facts relating to their particular subject, but have avoided any reference to actual cases. It appears to us that the writers of the first class have given what will actually prove to be the most valuable contributions for those who will need to use this book as a work of reference. The chief subjects included in this volume are Death, Wounds, Poisons, and Life Insurance.

We shall content ourselves in this notice with a brief reference to a few of the most striking of the many new and interesting cases here recorded, and first we note that four of the so-called Whitechapel murders are given in some detail. At page 89 we find mention of the case of a newborn infant who was left in a basket in the street in January, and remained there for twenty-four hours, and being then found by a policeman, and supposed to be dead, was taken to an undertaker's, where after a stay of some hours it was found by the doctor to be still alive, and under appropriate treatment it rallied well, and lived for some time. In the section on wounds there are several cases of the utmost importance, and especially two of bullet wounds of the thorax, where the bullet lodged in the sacrum or low down in the back, and where this very unusual course entirely bore out the statement of the prisoner in each instance as to the circumstances under which he had fired the fatal shot. It is worthy of note, too, that in one of these cases the man had run a quarter of a mile after the bullet had passed through his right auricle. But the most remarkable case, and one which our readers must exercise their own discretion about accepting literally, is the following: "During the war of the Rebellion, a general officer of the Federal forces, riding in a fog up to a picket, discovered it to be the enemy. He wheeled his horse, and leaning down on him as far as possible, drove in the spur. The picket fired a volley. The general's horse carried him into our lines, but the general was dead. A bullet had entered the arax, leaving no mark of its entrance, and ended its course in the thorax."

In the section on the poisons we note a fatal case of iodine poisoning in a boy, aged 11, who died about four days after his mother had painted both his legs with a solution of iodine, strength not mentioned, but strong enough to blister them. In the very excellent account of arsenic poisoning we find the case of Mrs. Sherman, who was accidentally detected

on the death of her fourth husband, having also made away with some half-dozen or more children or step-children. But the case of a clergyman is even more remarkable, as he was able to continue to carry on his trade with impunity. On the death of the sixth wife of the reverend gentleman suspicions were aroused, and whilst the bereaved gentleman was preaching to large and appreciative audiences at a fashionable church in New York, inquiries were being made about him, which showed that his *modus operandi* was somewhat as follows: He would marry an elderly spinster with money, and then settle down in some country parish; in a short time he would spread rumours of his poor wife's indifferent health, and then she would fall ill, and, after vicissitudes of good and poor health, would die, having made her will in his favour; he would then insist on a necropsy, and immediately afterwards used to have the body embalmed by the local undertaker. Under these circumstances the local authorities felt that it would be useless to institute a prosecution, but the reverend gentleman getting wind of their investigations, left his fashionable congregation to shift for themselves, and retired to a distant part with bride number seven.

Poisonous and other putrefactive products are dealt with in a separate chapter, and the section on life insurance is full of interesting cases, for the subject seems to have been a fertile source of litigation, and to have afforded ample scope for the ingenuity of that not small class of people who are always on the look out for a chance to live by their wits rather than by honest means. If the second volume maintains the high standard established in the first, this work will certainly be entitled to take a permanent place amongst the recognised works on the subject.

NOTES ON BOOKS.

The Elements of Health. By LOUIS C. PARKES, M.D., Medical Officer of Health for Chelsea, and Lecturer on Public Health at St. George's Hospital. (London: J. and A. Churchill, 1895. Cr. 8vo, pp. 241. 5s. 6d.)—With so many books on hygiene, elementary and advanced, already in the market, the appearance of a fresh book on the subject naturally prompts a reference to the preface to see with what special design the new work is issued. In the little book before us "the author's main idea has been to give some simple yet practical information and instruction on the preservation of individual or personal health in the ordinary routine of domestic life." This idea has been well carried out. One of the claims to originality rests with the illustrations, which are by Mr. Henry Parkes, and are a welcome change from the diagrams usually met with in books of this kind. The subject matter is tersely written, clearly explained, and up to date. The book is essentially an introduction to an elementary knowledge of hygiene, matters relating to questions of public health, over which the individual citizen has little or no control, having for the most part been avoided. As an elementary manual the book meets a want; as a textbook it is doubtful whether it would be enough for any but the most elementary examination.

The Causes and Treatment of Lateral Curvature of the Spine. By RICHARD BARWELL, F.R.C.S., Consulting Surgeon to Charing Cross Hospital. Fifth edition, carefully revised. (London: Macmillan and Co. 1895. Crown 8vo, pp. 232. 5s. Illustrations, 6s.)—This is a revised edition of a book which was first published in 1868 and rewritten nearly six years ago. In its present form it is intended chiefly to bring under the notice of the profession the advantages of an instrument devised by the author for giving rapid and concise measures of spinal deviations, and also to show the results of a special treatment described as rachilysis. Mr. Barwell, recognising the fact that the reading of a book on this subject is likely to be regarded rather as a duty than a pleasure, has sought by relegating dry and technical details to the appendix to render this an evenly flowing and interesting history. We doubt whether, in spite of all his experience and the zeal shown in the study of this subject, he has fully succeeded in doing this. We congratulate the author on the good results of his treatment and the success that has

attended the publication of his book. Most patients, however, supposed to be suffering from this affection fall sooner or later into the hands of specialists, each of whom has his own pet and fixed method of treatment. The book in its latest form has been much improved both by the author's revision and by the excellence of many of the new illustrations.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS IN MEDICINE, SURGERY, DENTISTRY, AND THE ALLIED SCIENCES.

A VAPORISER.

We have received a specimen of the *Aroma vaporiser*, manufactured by the Aroma Manufacturing Company, of 27, High Holborn, London, W.C. It consists of a small oil vessel with a floating wick which supplies the heat; above this may be suspended at various heights a small pan into which hot water is poured, while the antiseptic or odorant to be used is poured into the upper cup which fits loosely over the water pan. This upper holder is notched, as shown in the illustration, to allow the water to be introduced into the water pan. By adjusting the pan in one of the notches, the rate of evaporation can be regulated. The construction of the apparatus is simple and ingenious, and it appears to be well calculated to answer the desired purpose. A full description of the vaporiser, together with the principles of its construction and use, will be found in Dr. W. H. Spencer's little book on *Inhalation*, published by the Scientific Press.

A SKIN-GRAFTING KNIFE.

MR. FREDERICK C. WALLIS, F.R.C.S., Assistant Surgeon to Charing Cross Hospital, sends us the accompanying drawing of a skin-grafting knife, which has been made for him by Messrs. Weiss and Sons. The blade is 8 inches long and 2 inches wide, and the handle is 5 inches long. He has had the knife in use for some time, and claims for it the advan-

tages that no force is necessary to cut the graft, as the weight of the knife carries it easily through; that a large graft can be made, as the blade is a long one; that the width of the blade allows the graft to be kept quite flat with the right side up, and that, being flat, either the edge or the back of the knife can be brought to any part of the wound, and the graft pulled into position directly without any fear of its rolling up or turning over.

THE TONSIL GUILLOTINE.

MR. J. H. MONTAGUE (New Bond Street, W.) writes: In the *BRITISH MEDICAL JOURNAL* of July 6th you notice a "presumed" improved tonsil guillotine, and in justice to the makers of well-known surgical instrument makers I respectfully submit that it is quite contrary to the correct pattern of Mackenzie's tonsil guillotine to make them with the defect complained of; and, personally, I can confidently say I never have made any except with the blades fully guarded when open. I invite an inspection of my large stock of these instruments, not one of which will be found with the defect complained of.

At the conclusion of his speech before the prorogation of Parliament on Saturday, July 6th, Lord Salisbury spoke as follows: "There is much to be done in revising the operation of the Poor Law, which no longer corresponds to the state of things which now exists, and which does not recognise the vast changes that have occurred since it was enacted some sixty years ago."

WATERBORNE TYPHOID: A HISTORIC SUMMARY OF LOCAL OUTBREAKS IN GREAT BRITAIN AND IRELAND, 1858-1893.

*A Report Prepared for the Parliamentary Bills Committee
of the British Medical Association.*

By ERNEST HART, D.C.L.,

Chairman of the Committee.

(Continued from page 53.)

EXCEPTIONAL SOURCES OF WATER POLLUTION.

ONE VERY peculiar case of pollution of water is reported by Dr. Beveridge, of Aberdeen, as having occurred at a dairy farm there in 1881 (No. 129). The cistern at the farm was situated in a corner of the cowshed, its contents being used for all dairy and byre purposes. Analysis showed the water to be pure prior to entry into the cistern, but to become highly polluted with organic material while in the cistern. All the 302 cases of fever occurring in the month of April were in consumers of the milk from this dairy, and no condition of the milk/cows could be discovered, after very careful examination, to account for infectivity of the milk by the cattle. No one taking other milk was attacked, and persons whose cans were not washed in the cistern water escaped the fever. The epidemic was sudden, but as widespread as the distribution of the implicated milk. During the progress of the prevalence Professor Cosser Ewart discovered in the milk organisms identical with those found in the cistern water. The case is interesting as showing that despite the patent fact that the water was the *vera causa* of the epidemic, there is no knowing in what manner the water obtained its infective quality.

CHANCE SOURCES OF WATER SUPPLY AND TYPHOID FEVER OUTBREAKS.

In a category not far removed from the chapter of accidents to which I have lately referred, come those cases in which chance sources of supply of drinking water have figured as cause of typhoid fever. Two such instances of use of water in a more or less accidental way I may quote in this connection. They occurred widely apart in point of time and position, namely, the one at Bristol (No. 79), and the other at Evesham and neighbourhood (No. 112); the first in 1876 and the latter in 1882. In the first, it was among the inmates of an institution that the fever spread, the immediate cause of the 500 attacks which developed being the chance drinking by some of the orphan children of the contents of a stream during one of their walks. The stream received the sewage from houses in some of which typhoid had occurred, and as a result of this consumption thirty cases cropped up simultaneously in the asylum in children having thus drunk of the specifically contaminated water. The disease once introduced, was kept going until 500 children had caught the infection out of some 2,000 in the asylum. Here, then, was quite an accidental usage of a water by thirsty children while out for a walk in a dingle near their house. And it has its lesson for other large aggregations of young persons when out of the charge of the attendants usually looking after them. The second instance was of a most exceptional character, having to do with the visitors to a regatta who, in some numbers, drank of the water of a well in a meadow near where the regatta was held, the well being contaminated with animal organic matter, and situate near a sewer. As showing how the disease was caused, I may mention that the infection was found to be present in eleven villages, the early sufferers being all of them users of the well on the day of the regatta, either in its natural state or in the form of beer-mixed with water. Not one case of fever occurred in the large number of persons who thronged the other frequented meadow. The water of the well showed on examination signs of undoubted pollution, but the use of its water was a matter of accidental congregation in the meadow in which it found place.

CAUSE OF FEVER DISTANT IN TIME.

There have been not a few instances in which the cause of

the outbreak of waterborne typhoid has been far distant in point of time from the result of its operation. I have already, in speaking of the action of frost and thaw on the spread of such typhoid, had occasion to mention the lapse of lengthy intervals between the disposition of the infective material which has later given rise to disease and the disease which has thus been created. It must indeed often happen that the one and the other will be somewhat widely separated, for the reason that climatic conditions have so much to do with the infiltration of the specific germs of a disease into the water. It will readily be granted that excrement cast on to dungheaps in a period of frost and in a time of heavy rainfall will reach an adjacent watercourse under the latter conditions much more quickly than when the surface of the ground is frostbound. We have again and again seen heavy rain causing typhoid epidemics by the action of the water newly fallen on the ground in its forward course either on the ground surface or with the subsoil water thus augmented, and acquiring a fresh impetus towards its natural level. To the instances under these headings I need not again refer; and with what has already been said on these points it will suffice if I give one instance in which neither frost nor thaw was in question, but where the cause was in existence in the spring of the year and the result was manifested in the summer. The case of which I am thinking is that of Swansea, which town, but not this outbreak, I had occasion to mention in another connection a short space back (No. 107). Here, as will be seen from the appendix, the outbreak with its 640 attacks was traced to the fouling of feeders of a reservoir by excremental pollution from a farm on the gathering ground of the service, the fever having occurred four months before the epidemic outbreak, the immediate agency being a heavy rainfall. Here, then, it is seen that though frost and thaw had no place in the delayed outbreak, yet rain had a prominent part assigned to it; and indeed it may be laid down that the majority of such delayed appearances of effect following on cause are accounted for in one of two ways, namely, either absence of much rain or frostbound specific poisonous material which needs only opportunity for access to drinking water. These considerations point to the need for careful tracing back of the meteorological conditions for some time precedent to the prevalence under investigation.

METHODS OF SPREAD OF WATERBORNE TYPHOID FEVER.

That there should be various methods by which disease tends to disseminate itself is not surprising; but this does not remove from the region of surprise some of the methods by which spread is brought about. In the numerous instances in which typhoid has been set going by the medium of polluted water we have generally seen the disease appearing first in those persons who partook of the implicated water to the entire exclusion of all others for periods of time varying with the attendant circumstances. In some—indeed in very many—the disease has run a long course before any secondary cause has been found operating; whilst in others again the disease has soon ceased to operate through the original agency by such action on the part of sanitary authorities as closure of wells, or stoppage of supply, or the like, and has then fastened on other channels by which to propagate itself, as, for example, the methods of excrement disposal, the non-disinfection of bowel discharges or of infective slops, the attention of the nurses on the patients to duties which lend themselves to contact with the public, or with matters which come to be used for the preparation of foods or drinks for human consumption. The appendix is full of these various methods of spread of the disease; but I should like to draw attention to one case in which spread was brought about by what looks on the face of it to have been gross carelessness. At Temple Cloud in Somerset (No. 191), there occurred an epidemic of a very limited kind, seeing that it consisted of only 11 cases; but the circumstances were interesting on account of the family history which is contained in the report which Dr. Deane Sweeting made on the outbreak. He states, for example, that in one house the evacuations passed by three young patients were emptied only in the morning, being retained all night in the room occupied by the sufferers, and that in addition to this filthy and dangerous practice the nurse did not wash her hands or clean her nails after attending to the children; and he states

also as his opinion that the woman probably thus derived her infection. Moreover, no disinfectants were used at this house. The same condition obtained in other cottages in this outbreak, and the lesson to be learned as to the absolute need of perfect cleanliness is one that should be well taken to heart, not only in connection with typhoid, but in regard of all sick rooms, since, if we argue by analogy, we may expect to find a nurse who is careless about her own personal cleanliness, careless also about her patients; and in the sick room most assuredly cleanliness is next to godliness.

There is another method of spread of waterborne typhoid to which I shall have occasion to refer rather fully presently, and that is by means of foods rendered poisonous by polluted water, the chief of these being milk. If it seems odd to any of my readers that I should have included in the Appendix cases in which milk has played the chief part of spread, I would beg leave to state that I have given only cases in which the milk was primarily infected by means of specifically infected water, used either in the washing of milk utensils or in other fashion about the farms and dairies whence the infected milk was distributed; and I hold that these are as much waterborne outbreaks as are those where water is consumed in its natural state. But for the polluted condition of water used in the preparation of food for man these cases would never have had to be chronicled; and, indeed, their presence is a great stain on the state of sanitation in our country, since I opine to the view that our farmsteads are a standing disgrace to us in only too many instances, seeing that from them we derive one of our most staple articles of diet under conditions which are an invitation to disease in far too many places. Again, there are instances on record in which other drinks have been infected by the addition of polluted water, as witness the case of the Evesham regatta (No. 142), where the well water was not only partaken of in its natural state, but was also used for purposes of making lemonade and for mixing with spirit. I might name other methods of spread outside the mere consumption of the water as such, but the table in Appendix furnishes the means of finding them if any of my readers care to carry the matter farther. One point, however, I should like to mention before I pass from this subject, and that is that the occurrence of a large proportion of cases in any given outbreak in persons who have not drunk of the polluted water does not necessarily constitute any weakening of the argument as to the water having been the original cause. There are those who would have us believe that if a given percentage of attacks does not occur in the water drinkers, then that the water was not the means of bringing the disease into existence in the particular instance. Such people forget that there are in every epidemic, almost without exception, secondary causes operating at some stages, and it may indeed be precedent to the use of the polluted water. That this has happened in the past I do not doubt, and that it will happen in the future to an even larger extent I feel quite certain, seeing that compulsory notification will give sanitary authorities an immense pull over their earlier predecessors, who laboured under the disadvantage of ignorance to a large degree of the dimensions of an outbreak, and did not in too many cases know of its presence until it had attained the proportions of a dangerous prevalence. Where the circumstances are favourable to the early detection of the polluting agent, and the water is cut off or the means of its contamination removed, then it is pretty certain that the number of cases will be small in water drinkers as compared with those in non-water drinkers if the epidemic be a large one, and there are other means of spread of the disease at work in the district, as we have too often seen in past outbreaks. Let me name a few such examples:

At Wing, in 1863 (No. 1), fever was kept going owing to the prevalence of insanitary conditions, altogether apart from the polluted well. A typical case is that of Winterton, in 1867 (No. 7), where the disease was associated with the drinking of polluted water, but where, to quote Dr. Thorne Thorne, "Given the existence of typhoid fever in a town, it is hardly possible to conceive conditions more favourable for its spread than these existing at Winterton." Another inquiry held by Dr. Thorne Thorne in which local conditions other than the water were in operation to cause the spread of fever was that of Radford, in Netts, in 1870 (No. 23), where the epidemic,

having been set going by means of water, was kept up by the means of excremental contamination of air and soil, specific material being cast into the streets or middens near dwellings or stored in ill-ventilated houses. Coming to more recent times, I may refer to the case of Northallerton, in 1892 (No. 193), where the disease can be thought of as having in some measure been kept going by the poisoning of air by the sewage-saturated ground. And lastly, not to tire my readers by unnecessarily numerous references, I would draw attention to the instance of Atherstone, in 1893 (No. 196), where the incidence on the consumers of the polluted water was as high as 87 per cent. during the epidemic period, but where the disease, once fairly established, had the prevailing midden system to aid it in its successful attempts to propagate itself, the system in vogue lending itself to such dissemination as actually occurred.

WIDESPREAD INFECTION OF TYPHOID FEVER.

An instance in which the infection of typhoid was of a very widespread nature was that of the three villages of Aylstone Park, Whetstone, and Narborough, in the Blaby Rural Sanitary District, in 1880 (No. 110). No fewer than eleven groups of attacks occurred in these villages, to the exclusion of a fourth village in the vicinity where the nineteen cases which cropped up were related to specifically infected midden privies and poisoned air. What was still more curious was the fact that the initial case in each group served as the cause of spread by means of the disposition of the evacuations in a way readily to contaminate a well. The cases to the total number among water drinkers of 211 occurred in the immediate vicinity of the several wells thus subjected to pollution. Users of other wells were entirely excused from infection except in the case of the fourth village just mentioned. This instance of widespread results following the disposal of the excreta of only a few cases to my mind raises very decidedly the whole question of excrement storage in our country parishes. The close relation of our drinking water and our midden contents is a matter of the greatest importance, and people seem seldom to realise that filth and disease are synonymous terms until taught the truth by some such bitter experience as at these villages.

SHORT-LIVED TYPHOID FEVER EPIDEMICS.

It will be observed, from the tabulated statement at the end of this report, that there are all sorts of epidemics recorded in regard of period of duration, some being prevalences long drawn out, and others again those of brief operation. Of the latter class I may mention the case of Swansea in 1879 (No. 107), where the cause of the outbreak was itself apparently of short duration, a uniform rise taking place in all the districts affected, namely, in the third week of the epidemic, with equally uniform decline from that time until the end of the fifth week. Yet another case of a brief but sharp prevalence was that of Pentraese, in Cornwall, in 1873 (No. 59), where no less than 28 per cent. of the consumers of the water causing the fever (71 cases in a population of 358, of whom 235 used the well) were attacked in the month of August. At Tregoney, in the same locality, there occurred over 50 cases in December, 1873 (No. 64), in a population of under 800, and some of these derived their infection from secondary causes. The case of the Orphan Asylum at Bristol, already mentioned in connection with chance sources of water supply (No. 79) was one where the primary cause was quickly arrested, and where the disease should have also been at once checked, but where, despite the continued spread of the fever in the institution, the epidemic of 300 attacks was over in a couple of months. Hitchin furnishes another example of short epidemics (No. 144), for there were two outbreaks in the two months of December and January, 1882-83, each of some amount, totalling to 100 cases in all. On the other hand we have in the accidental prevalence at Perth (No. 112), in 1880, an epidemic lasting from May to November, although the primary cause was only of one day's duration. I might quote additional instances, but those here set out suffice to make my point clear.

WATERBORNE TYPHOID FEVER AND "ABSTAINERS."

In epidemics of waterborne typhoid it is only natural to think of total abstainers from the use of alcoholic liquors as

suffering in proportions exceeding persons who make but little use of water in an unboiled state. Of course there will always be a large and major portion of the general community who, while consuming water in part in its natural condition, make use of it also in a boiled form in their daily beverages, in addition to those who also partake of other drinks to the exclusion of water in great measure. But in not a few instances the excessive incidence of attack on abstainers has shown beyond doubt that the drinking water has been at fault. Let me illustrate my point. At Bramham College, near Tadcaster, there occurred a prevalence of typhoid in March, 1869 (No. 12), 19 cases resulting as a consequence of the pollution of the water supply of the establishment by way of a defective closet pipe. Nearly all the attacks were in total abstainers, who were the chief, if not the only, abstainers in the college of 60 or 70 persons. In the succeeding month of the same year, at Ackworth Moor Top, in Yorkshire, there was an epidemic (No. 13) arising apparently from infiltration into the well of the village of excreta from the initial case. I have not been able to find out the exact number of cases, but an institution was involved in the outbreak, one that was carried on upon teetotal principles. Both in this institution and outside total abstainers were the first attacked and also the most numerous. These are but two instances culled from many that figure in the annals of waterborne typhoid; and the matter is not astonishing, but calls for the remark that what is needed in these, and other persons also for the matter of that, is that all drinking water should be boiled.

EFFECTS ON TYPHOID FEVER OUTBREAKS OF BOILING POLLUTED WATER.

Following on what I have just said, it will be interesting to consider the evidence which is available as to the influence on typhoid prevalences of the boiling of drinking water, if such evidence be forthcoming. Such evidence is, as a matter of fact, not difficult to find, and I will therefore adduce some of it in support of the practice. As long ago as 1864 the benefits of boiling water were pointed out by the late Dr. E. Seaton in his report on an outbreak at Page Green, Tottenham (No. 4), where in a row of five houses dependent upon local wells all the houses were invaded with one exception, where, namely, the inmates "first boiled all the water which they used for drinking." At Buckingham in 1883 (No. 168) the decline of the disease, which had been waterborne, was attributed in part to the precaution of boiling the implicated water, as reference to the report of Dr. Franklin Parsons shows. Perhaps the most unique instance of the boiling of drinking water in the face of disease is that recorded by the late Dr. David Page in connection with an outbreak of typhoid, undoubtedly waterborne, at New Herrington, in county Durham, in 1889 (No. 179). With a view of guarding against further distribution of the disease by means of the polluted supply, the water of another service was turned into the mains; but this not sufficing in point of quantity, Dr. Page said that "arrangements were made and actually carried out for boiling the supply pumped from the Herrington well before it entered the reservoir.....On the occasion of my final visit.....I witnessed the remarkable and unique instance of delivery to the mains of a water supply which had been actually submitted to a boiling temperature." Again, Dr. Bruce Low points to the fact that in the village of Nunington, in the valley of the Rye, the fever ceased to attack the residents a fortnight after the issue of a warning to boil all drinking water. In reporting on the use of the Trent water for domestic purposes in relation to the incidence of typhoid on riverside populations (No. 174), Dr. Bruce Low states with reference to certain villages having but little typhoid, that their escape may be thought of as having to do with the use in them for drinking purposes of boiled water only. Indeed, in the district generally the medical men have done much apparently to stay the spread of typhoid by their counsel as to the boiling of the river water. And though I have made mention of Nunington only in speaking of the Rye-side fever, Dr. Low thinks of other villages as owing their immunity from the disease to the same practice as obtained in that village. It will be evident from what is here said that the precaution is not by any means overlooked in the actual presence of the disease, but I much fear that the measure is too often neglected

among our people, especially in our large towns, where persons seem to fancy that there must be safety, by reason of the water undertaking being in the hands of some body corporate or the like. But if the circumstances relating to the filtration of some of our water services in even the largest towns in England were to be made public, I doubt if we should be as a community so disposed to place blind trust in our water companies. The expedient of boiling the quantity of water needed in an uncooked state each day is a simple one, and the necessary quantity to be so treated can soon be gauged. Prevention is not only better than cure, but in this case at least it is infinitely cheaper.

SANITARY INACTIVITY AND ITS RESULTS.

Where so much could be said on this subject it is difficult to quote examples. In modern times the glaring instance of Rotherham stands out very clearly (No. 190), and I have already referred to the conditions which have long held in that town in relation to water supply. Dr. Theodore Thomson, in reporting on the cholera experience of 1893 there, said: "Rotherham had in 1891 actual experience of loss of life and health from fever due to specific pollution of the public water supply, but the sanitary authority do not appear to have profited by the lesson." I need not dwell further on this case, save to say that the medical officer of health states in his annual report for 1894 that the much polluted "Well-gate spring" has at length been closed, with beneficial results already apparent. Equally to the point is that of King's Lynn, of which place Dr. Bruce Low said, in reporting on its fever outbreak of 1891 (No. 189): "The dangerous condition of the King's Lynn borough water supply has been, time after time, pointed out by the medical officer of health and by others. The urban sanitary authority has more than once proposed to protect the water by piping it from a spring or springs, but this project has always hitherto been defeated by a section of the ratepayers who, ignorant of the dangers arising from the pollution of potable water by filth, regard the present supply as all that can be desired." Dr. Low adds the following interesting footnote to this sentence:

"Mr. W. Whitaker, F.R.S., of H.M. Geological Survey, in a presidential address to the Norwich Geological Society, delivered as far back as November 6th, 1883, and published in the *Geological Magazine* of January, 1884, drew attention to the Lynn water supply while discussing certain points in connection with drinking water derived from chalk springs piped to certain towns in Norfolk, as follows:

"The enterprise of Wisbech is thus in strong contrast to the apathy, and one may say the stupidity, of the larger town, in which I have the misfortune to live, its Norfolk rival, Lynn, the corporation of which treat the inhabitants to one of the worst supplies that I know of. These guardians of the public health allow a set of chalk springs, some pure, but others contaminated, to mix together and to flow along an open channel of six miles or so, as the crow flies, receiving on the way the drainage of a fair tract of country, and at the last, close by the borough boundary, some part of the sewage of the village of Gaywood. Notwithstanding that the evil of this course has been pointed out for years, and constant complaints occur, yet our town councillors, in the multitude of whom there is not wisdom, have not yet made up their minds to any decided action, and a question that really admits of no debate is the subject of apparently endless discussion. "Words, not deeds," should be the town motto, at least as far as regards the water supply."

"Since the above paragraph was written the town council of Lynn adopted a scheme for the supply of good water, but I fear in a half-hearted way; at all events, their scheme has been rejected at a meeting of the ratepayers, and I am therefore compelled to transfer the charges above made from the members of the town council to the body of the townsmen, who seem not to be educated up to pure water pitch! When they have had a serious epidemic perhaps they may acquire more sensible views on this matter." It is matter for congratulation that the health body have since seen the error of their ways.

At Appledore, where an outbreak of typhoid occurred in 1870 (No. 24), the conditions were disgraceful at the time, and such as to lead Dr. Thorne Thorne to state that "had the town been specially designed to favour outbreaks of

typhoid fever the result could hardly have been more completely attained than has been the case at Appledore. The report teems with instances of sanitary neglect. At Oldbury the same writer shows a deplorable state of affairs to have existed in 1870, when fever prevailed. His own words best describe the place as he found it at the time:

"Wells are in many instances placed within a few feet of one or more privies and open middens, which are little better than reservoirs for liquid and excremental filth. Some parts of the township are without any water supply, and hence the inhabitants have either to travel a distance of sometimes half a mile to neighbouring springs or they buy it as often as they can afford it of persons who regularly bring it round for sale. This deficiency of water is a point of the most cardinal importance; it deprives the poor of the principal means of keeping themselves and their premises clean, and it must be considered as one of the prime predisposing causes of disease. The poor themselves urgently beg for a proper supply; some informed me that they were compelled at times to resort to the canal, which is in reality the main town sewer, in order to wash themselves; and on several premises I found that lumps of ice and masses of snow had been collected, and were being melted down for domestic use. The want of water has also, in a peculiarly offensive manner, been a cause in spreading typhoid fever, for during the past year some of the inhabitants have been compelled to wait until a rainfall before the linen of the patients could be washed; and the amount of unwashed and poisonous linen which has thus accumulated has, I am informed, in some houses caused an almost unbearable stench."

And here, be it remarked, I am only quoting one short passage to indicate the sort of place it was in which fever thus settled. It may be asked why I go so far back in order to get my instances of sanitary inactivity. My reply is that I have made reference to 2 cases of ancient and 2 of modern history. I do not see my way to showing up the deficiencies of sanitary bodies to any great extent lest I should weary my readers by iteration of much that is already contained in the preceding pages under other headings. The inactivity of our so-called health bodies need not be specifically spoken of as such to enable my readers to grasp the fact that nearly all that is here written is the history of neglected opportunities which, having been allowed to pass, have carried in their train the loss of life and the suffering which are here set out. It has been truly said that cholera saves in our country more lives than it destroys, for the reason that people are stirred up into activity in matters sanitary when that disease threatens or fears of its presence prevail, more than by the fevers that are now endemic among us. But since typhoid has ceased to have for us the horrors that are implanted by a disease which is far less fatal in our midst, these recurring outbreaks which are here chronicled continue to claim their victims. If one death by Asiatic cholera occur in a town, there is an immediate outcry on account of the danger that threatens the place, and people are forgetful of the patent fact that the conditions which operate for the spread of cholera are just those which favour the dissemination of typhoid. Not until the public come to see and understand that the truest economy lies in the reasonable expenditure of money on that which goes to remove the causes which lead to the spread of preventable disease, and which bring death and suffering and distress in their wake—not until then will our death-roll show that diminution in its total which is attainable.

COMPULSORY NOTIFICATION: ITS BENEFITS IN RELATION TO TYPHOID FEVER.

It is probably not necessary for me to say much on this subject, looking to the strides which have been made elsewhere in the way of settling the question of the utility of compulsory notification. Our country has decided in almost all its districts that such a system is necessary for the due safeguarding of the public health. The Infectious Disease (Notification) Act, 1889, has worked in a marvellously smooth manner, and has been a marked success. It stands to reason that if the early cases of infectious disease occurring in a district are made known to the sanitary officers at once on their arising, the chance of curtailing the spread of the disease is much more probable than if cases are allowed to

give rise to others before attention is drawn to them by some such development as a fatal attack. If the system of notification is in force and proper hospital accommodation be behind that system, the district thus provided is in a fair way to check chance cases of infectious disease from growing into widespread epidemics. Let me give two or three references to reports which show the desirability of prompt notification. The one is that made by Dr. Deane Sweeting on the outbreak at Temple Cloud in 1891-92 (No. 191), in which the writer states that, early cases of typhoid not having been notified, the health officer was not enabled to see that proper precautionary measures were taken, and, as a matter of fact, it was in this district that there occurred spread of typhoid, owing to great want of proper regard to cleanliness in the sick rooms, as I have already taken occasion to show. The other report to which I may refer in this connection is that of Dr. Gresswell on the outbreak at Hedden Bridge in 1894 (No. 155), wherein he states as follows: "The importance of prompt notification and ready means of isolation in Hedden Bridge can scarcely be overrated." And he proceeds to refer to the local circumstances which went to favour the spread of the disease in the absence of such prompt knowledge of cases as should have been in possession of the health officer in order to enable equally prompt measures to be adopted. Overcrowded cottages, the working of members of infected houses in factories and like aggregations of persons, and other circumstances conducing to dissemination of infection, even though enteric fever was in question.

A case very much in point was that of the Gainsborough rural district, wherein Dr. Bruce Low made inquiry as to the use of Trent water in relation to enteric fever (No. 174). He found that compulsory notification was not in force in the district, and this meant for him much trouble in addition to the feeling that when all was done that seemed possible in the circumstances, he could not be at all certain that all cases of fever which had arisen were accounted for in the lists which were prepared for him. It will be well to give his own words:

"Finally I obtained, after the expenditure of much time and trouble, particulars of cases from all the medical men living and practising in the different parts of the rural district. I soon found that my inquiries would have to be limited to the last four and a-half years. The lists had to be prepared in some instances from memory, with this result: Where a practitioner was having groups of cases every year, some of them club patients of whom no record was kept in ledger or day book, the lists of actual cases were admitted to be complete; but where, on the other hand, the medical men met with sporadic cases only, sometimes not more than one in two years, the facts as to each occurrence remained in their memories, and their lists of cases were much more complete. I have considered it right to make this statement, as farther on I shall have to point out an inequality of incidence of enteric fever in certain localities, the inequalities being for the above reason even more pronounced, so it is believed than is shown by the figures. A consideration of the two sets of figures will show that the sanitary authority were imperfectly informed as to the amount of preventable illness occurring in the district under their care, and that consequently their officials, no matter how active or willing, could not take the necessary steps to check the further spread of the infection. This insufficiency of information might have been obviated more recently had the rural sanitary authority adopted the Infectious Disease (Notification) Act of 1889."

Dr. Low's report is dated 1893, but in another presented to the same Department in September, 1894, on scarlatinal prevalence in Hucknall Torkard, Dr. Thomas Horne has much the same thing to say of the non-adoption of compulsory notification there. Proceeding to discuss the data of the epidemic, he says:

"As to the actual number of non-fatal cases occurring in the district definite information is not, in the absence of notification, forthcoming. The medical officer of health says in a special report on the epidemic which he presented to the sanitary authority, 'It is certain that only a small proportion of the cases were brought to my knowledge.' And again, 'owing to the fact that only a small proportion were notified to me, I am unable to give the number of non-fatal cases.'"

But no one will quarrel with my assertion that the adoption

of compulsory notification is a safeguard against the spread of infectious disease, if its information be used aright, hospital accommodation especially entering into the organisation by means of which epidemics are to be successfully combated.

WATER-INFECTED MILK AND TYPHOID FEVER.

The relationship existing between dairies and milkshops and the like on the one hand, and the prevalence of typhoid on the other hand, is now admitted to be very close. It was not so admitted a quarter of a century back, when, indeed, the relationship was all but ignored. Writing on the whole subject of the influence of milk in spreading zymotic disease in 1861, I stated that the spread of such disease by the agency of milk was then almost a new danger revealed by hygienic sciences. Ordinary measures of sanitary (domestic) precaution did not seem to avail to secure immunity against the incidence of disease so spread, although the bearing of milk was seen to be a method of rendering that article innocuous. Upwards of twenty years' experience of milk-disseminated diseases has not led to any general observance of this simple safeguard against those epidemics which still from time to time startle the public by claiming victims from all classes of society by reason of neglect of the precaution of seeing that all milk is submitted to a boiling heat. Many a mother has had cause to sorrow over the neglect of her cook in carelessly omitting the injunction given to treat the milk in the way indicated. As a result of such carelessness the lives of only too many innocent children have been sacrificed, and the sorrow thereby caused has not been in any wise softened by the knowledge of the fact that but for the business—I might almost say criminal inaction—of some domestic servant the life taken would in all human probability have been saved. Not that I would be thought of as even seeming to throw the blame for milk epidemics on householders on account of the omission of this precaution, by no means. I simply state that things being as they are it is the duty of every housewife to see to it that the family milk service is treated as an infected commodity. That it should be necessary for such action is my chief complaint, since the condition of the milk trade, to my way of thinking, should be such that this act on the part of householders should be unnecessary. It is indeed against the vendors of our milk supply that I inveigh. The state of a vast proportion of the places whence milk is sent to our markets, and the state of only too many of the shops where that milk is retailed, is a disgrace to our nation. One cannot take up a report on any rural district without reading of circumstances attending the sale of milk from farms which are highly provocative of disease; and I am not here referring to times long gone by. On the other hand, I have in my mind instances where the conditions attaching to dairy farms have been most grossly insanitary within quite recent years.

But before I go into the matter any further in a general way, it may be advisable for me to refer to some actual instances in which disease has been traced to milk infected with the specific germ of typhoid by the agency of polluted water. I need not weary my readers by numerous references, so I have taken samples to the number of six from the appended tabular statement with the object of showing some of the ways in which milk is subjected to hurtful surroundings.

At Moseley and Balsall Heath, near Birmingham, in the winter of 1872-73 (No. 52), it was found that of 50 households invaded by typhoid as many as 47 were consumers of a certain milk service, and that at the premises of two adjacent milk sellers the conditions were such that there could be little doubt as to the source of infection of the milk distributed. Midway between two dairymen's premises was a house in which a case of typhoid occurred, the dejects being cast into a pervious privy in such manner that the contents of the wells serving the houses in question could hardly escape contamination. The water of the one well was used by one of the dairymen for purposes of milk dilution, whilst the milkman on the other side made no profession of selling pure milk. The evidence against the milks was more telling even than that adduced by the above data, since no other cause of fever could be found, and use of the milk of other vendors, even in the same street, was attended by no untoward result.

At Crosshill, in Renfrewshire, in the early months of 1875 (No. 77), there occurred an epidemic of 183 cases, and related

unmistakably to a particular milk service. The water supply of the farm whence the milk was sent was from a well situated close to a large collection of liquid refuse, and itself supplied from a spring dangerously situated in respect of a ditch, into which ditch, moreover, or on to an adjacent manure heap, the dejects of some typhoid cases had been cast.

A somewhat curious case of water-polluted milk was that of a village near Leeds, in the summer of 1876 (No. 87), where some children of a household of ten persons were attacked by a lingering illness of a typhoidal nature. The single cow kept for the purpose of the domestic milk supply had during some months been getting thin, at last refusing to graze. Her water supply was a stream into which a watercloset drained, and which became "mere sewage." The cow was at length sent away, and thereafter not only did no fresh case of illness occur at the farm, but convalescence set in, albeit of a very tardy character. This instance of, so to speak, transmitted typhoid through the milk cow, is one of much interest. The prominent feature of the series of cases was the lingering nature of the illness contemporaneously with the same tedious ill-health of the cow. It and the instance of the outbreak of the Glasgow Hospitals in 1884, already spoken of in discussing the relations of excrement to typhoid, are the only cases of this kind that I have come across in my study of the subject. In the summer of 1888 an outbreak of typhoid occurred in the village of Millbrook, in Cornwall (No. 113), which has become historic by reason of the prominence to which it attained at the time owing to the report made to the Medical Department of the Local Government Board by Dr. Ballard. The case in relation to milk was what may be called one of indirect infection, since there was no direct communication of contaminated water and milk, the circumstances being as follow. Imported fever having led to specific infection of a street sewer, this in its turn led to contamination of a well through the medium of an overflow pipe. This well caused typhoid in some of those drinking of its water, and the patients' dejects were discharged by way of privies to a drain which had aerial connection with the room of a dairy farm wherein the milk was stored on shelves, the milk in this manner being exposed to the emanations of the specifically infected drain, with extension of the fever as a result in members of the dairyman's family, and an unknown number of his customers, twenty-two of whom were traced as having suffered. In this case the sale of the milk was never stopped, and the disease went on "until," to quote Dr. Ballard, "the whole village has become steeped with the contagium." If it be in any wise contended that this is not a case of water-infected milk causing typhoid, at least it cannot be set aside as a typical instance of water-borne disease, and hence finds fitting place in the appendix. I am, however, content to see it here mentioned in the category of milk-typhoid outbreaks, and to regard water as having played an important part in bringing about the infective quality of the implicated milk. I will only give one more reference to the appendix in this relation, but it will be to a case of most gross inattention to the first elements of sanitation, since it deals with an outbreak which was brought about by means of water which should never have been for one moment thought of as usable for any purpose whatever in connection with the preparation of food for the use of man. The occurrence took place at Great Coggleshall in the winter of 1886 (No. 90), Dr. Thorne Thorne being entrusted with report on the matter for the Local Government Board. He found after inquiry that the undisinfected discharges of a typhoid patient had been cast into a drain which found outlet into a brook, the water of which, only a few yards below the drain outlet, was used for dairy purposes. All the cases of typhoid to the number of 38, arising from consumption of the milk of this one dairy were among persons who had nothing in common save their milk service, and not one case arose outside this milk service, notwithstanding that there were four milk vendors in the town. The details of a story like this fill one with disgust, which is in nowise lessened by the thought that the milk on one's breakfast table may be merely that which it purports to be plus an unknown quantity of typhoid excrement. We live in times not one whit nearer the perfection of dairying from a sanitary view point than when this outbreak happened over eighteen years back. Let me give two or three

instances of the conditions prevailing at our dairy farms in recent times.

Mr. Harvey, in reporting for the Local Government Board in 1886 on an epidemic of typhoid at Swanage (No. 163), says of the dairy implicated in the spread of the disease there that it, "like all others in Swanage, has been under no sort of regulation or supervision, and in the circumstances of its water supply there would appear to be sufficient explanation of the method of infection of its milk. Its water supply is nominally from the pond near the church, but as a matter of fact it is without a supply of water, unless, indeed, the brook is to be thought of as furnishing such supply. . . . Certain it is that the water of the brook, from the moment of its approach to the town and far above the dairy, became eminently fouled by the overflow of drains and other circumstances." Surely this is a case as gross as that of the previously-named farm at Great Coggeshall. And again, Dr. J. H. Garrett, in reporting on the sanitary condition of Cheltenham in 1893, says of the premises of two milk-sellers in that borough, "Here again, however, as in the former instance, a polluted water from a well upon the premises . . . was used for washing the milk utensils." And from this statement we see that if our milk supply be saved from pollution at the farm in the rural district, it by no means follows that it will not be exposed to dangerous contamination at our very doors. I was much struck on reading a report by Mr. T. W. Thompson, presented to the Medical Department of the Local Government Board in December, 1892, on the general sanitary condition of the York rural district, by the description therein given of the state of dairy farms in different villages in respect of their water supply. Thus, at one farm at Beighton the well was partly under a corner of the house and only some four feet from the foldyard, "the well was only dry stoned, and doubtless served to drain the foldyard." Then, again, a farm at Fulford Water derived its water from a well close to the foldyard. At one farmhouse in the village of Copmanthorpe the only source of water supply was from a pump well in the middle of the foldyard, the water of which well tasted of the "oil" from the wooden covering of some adjacent creosoted red pine roofing after a rain storm, the first following upon the erection of the roofing. These, then, are some of the instances which were found to be existing in this district surrounding the city of York. Proximity of the farm wells to foldyards was a commonly-found defect in the district, and with the generally unsatisfactory state of the surroundings of wells all over the area the pollution of milk by the medium of water is not unlikely to frequently happen. In the neighbouring county of Lincolnshire we find, from the admirable report by Dr. Bruce Low on the Trent in relation to water supplies of the populations situate on its banks (No. 174), that in the rural district of Grimsborough, at some farmhouses on the river banks, "the water is pumped direct from the Trent to the house through a leaden pipe through the bank into the bed of the river." When one takes into account the highly polluted state of the Trent, subjected as it is in its whole length to gross excremental contamination from large aggregations of population, it is difficult to see how an unpolluted milk supply can be expected to emanate from the farmhouses where such a stream is the source of the water used for dairying purposes. I have already referred to the condition of this river, and need not here recapitulate the disgusting catalogue of pollutions to which it is open.

In illustration of the statement that it is not in the present time difficult to find a condition of affairs as bad as those just described, but existing in retail premises in our large towns and cities, I may mention the experience of the city of Edinburgh in the matter of the sanitary state of the milk-shops there. In January, 1894, the Public Health Committee had their attention called to the serious condition of these premises for the retail sale of milk, inasmuch as it was found that many had their sleeping and living rooms in aerial communication with the rooms in which the milk was stored prior to sale. But worse still, many had these milk store-rooms in aerial communication with water-closets in the house, and in all it was found that some hundreds of the 760 retail vendors of the commodity had such dangerous inter-communications existing. It was, of course, not a state of things to be tolerated, and the Committee in the first place took steps to warn the poor people who eked out a living by

the sale of small quantities of milk that either alteration of their premises must be carried out for cutting off the common atmosphere of the house from the milk storeroom, or they must desist from the selling of milk. As a consequence, a very large number of the shops were closed to the sale of milk, the people contenting themselves with the vending of the other articles which formed the staple stock in trade.

There is here, then, not only an instance of the deplorable state of things existing in a populous city, but also one of the value of mere verbal or written notice to even the poorest persons engaged in trade that they must seek to ameliorate the conditions under which they are carrying on their business to the danger of the community. But no one can read this account of the Edinburgh smaller milkshops without seeing to what a risk the city was exposed by reason of having a commodity so absorbent as milk open to the reception of drain air and other abominable stinks in a poor and populous quarter of the town. A food of such essential importance to the infantile population of a town cannot with impunity be allowed to be sold in a state of possible infectivity.

Turning to quite a different part of the country, I find Dr. Timbrell Bulstrode, in his report to the Local Government Board on the sanitary condition of Poole, giving an instance of a cowshed in that town in an insanitary condition. He tells us that it had not been whitewashed for a year, that it was dilapidated and dark in parts, and that immediately adjoining it was a huge accumulation of manure, at a higher level than the cowshed. In addition, the floor was defectively paved, and abutting upon the cowhouse was a double privy containing a vault which had not been emptied within the last year. He adds: "It was amid these surroundings that the milk supply of the customers was drawn from the cows."

I need not go further into details on this matter of the insanitary state of dairy farms and milkshops in our country, since if I say that the examples given of bad sanitary conditions are but typical of much that passes to-day as sufficient to warrant non-interference on the part of so-called health bodies, I think I have shown that we are still far from having arrived at that state of sanitary perfectness to which it should be our aim to attain. Milk is a food which is in great demand by the public at large, and especially in demand on account of the share which it takes in infantile feeding. Absolute purity of the commodity is accordingly correspondingly essential. It is bad enough to have a milk service which is far below the standard of the article as it is yielded by the cow, without the added horror of a supply mixed with water which is more or less of the consistency of sewage. If water of even the slightest doubtfulness is used for can-washing purposes, we have a right to demand that it be first submitted to boiling temperature; whilst if our farmer is so dishonest as to dilute his produce, we have at least good reason for claiming that the water paid for as milk shall be free from suspicion of contamination. Water of any kind at fourpence a quart is dear, but the pure article is preferable to the contents of a ditch or the ooings of a midden privy. And here for the moment I must leave this matter, hoping to treat of it again in my final recommendations.

[To be concluded.]

DEATHS UNDER ANÆSTHETICS.

CHLOROFORM.

Dr. JOHN BROWN (Bacup) writes: It would appear that the number of deaths under chloroform is gradually on the increase. May I be allowed to again urge the chloroformists at our large metropolitan and provincial hospitals to give the "slow method" a fair and honest trial, and compare the results with the "rapid method." After several years' experience I published an article "On the Advantage of Producing Anæsthesia by Small and Continuous Doses of Chloroform." My experience since has strengthened my views. In the *Æsclepiad* there is an article by Sir E. W. Richardson on "Accidents under Anæsthetics," which I trust will command the serious attention of our medical schools and hospitals, and those who have to train the students how to give anæsthetics. I never saw the "slow method" in any of the

hospitals, and I believe most men commence practice with the idea that complete anaesthesia in five minutes is the true ideal of a good chloroformist. Sir B. W. Richardson says: "My experience is that the correct way of administration of chloroform is to give the vapour properly diluted, and that the theory of pushing the vapour so as to get a rapid anaesthesia at all risks is as dangerous a plan as could be possibly devised. I can but look upon the excessive mortality which has followed administration as largely due to what must be considered a practice rough, ready, and venturesome." Rough, ready, and venturesome fitly describe the present method of administration.

REPORTS

ON

THE NURSING AND ADMINISTRATION OF PROVINCIAL WORKHOUSES AND INFIRMARIES.

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

L.—BEDFORD.

THE workhouse stands on the outskirts of the town, surrounded by extensive grounds, part of which is garden and part kept for hay. On approaching the building, there is nothing to indicate the workhouse, nor is there the porter's lodge to guard the entrance—indeed, ingress and egress on the part of anyone would be quite easy. The building itself is of ancient date. We were informed that it was built some time in the last century, and is one of the old houses of industry of that period. Within we found the lofty rooms and large windows that marked this period, before the cramped and squalid style of the early part of this century came into favour, when the window tax prohibited the entrance of light and air into the houses of the poor. The guardians having given ready assent to our request to go round the wards, Dr. Prior, medical officer to the house, most courteously placed himself at our disposal.

THE SICK WARDS,

as we expected, though of lofty construction and having an ample supply of light and air through the large windows which faced each other, are antiquated in their appointments and arrangements. The beds, facing each other round the walls, are of good width; some of them have spring mattresses; on the remaining beds there are flock beds, and straw is used for special cases. We found the usual deficiency of comfortable chairs for the inmates; some wooden arm-chairs without cushions, plain chairs or benches, a deal table, and a table-locker between the beds completed the ward furniture. The wards are warmed by open fireplaces, one or more according to the requirements of the room; fresh air is admitted through the open upper sash, which, as Dr. Prior said, is excellent in theory but defective in practice when the doctor's back is turned. The number of sick is difficult to arrive at, as the aged and the sick are mixed up together; but so far as we could make out there were beds for between 60 and 70 patients, and these are distributed in two wings on the first and second floor.

On the first floor is a ward of 13 beds, and above a similar ward for the sick, and adjacent a ward of 16 beds for the aged men or women; this latter ward looked crowded, the beds being close, but as there was no statement of cubic area on the floor we were not able to verify our suspicion. On the female side on the second floor is a small room containing three beds used for lying-in cases, and another ward now used as a workroom. This appeared to be the only classification. There are no children's wards; when sick the children are placed with the adults. Those cases which have to be isolated, such as lock patients, itch, or erysipelas, are placed in small dreary wards in an isolation block at the back of the building. The females are attended to by the nurse on the female side, the males by the porter; as both these officers

are occupied with their respective duties in other parts of the building this attention must be nominal only.

There is, besides, a block for quarantining, containing two wards, these were tenantless and dreary at the time of our visit. The matron informed us that there was no regular system of nursing of the patients consigned to this block, it was sometimes done by an inmate and sometimes an outside nurse might be engaged.

THE NURSING

is divided between two nurses, one for the males and one for the females, with the usual pauper helps, and there is no night nurse. The nurse on the female side appears to be an assistant to the matron, as she has to leave the wards to see the materials for the dumplings weighed out; she also has to superintend the bathing of the able-bodied women and to superintend the women who may be at work in the workroom that is adjacent to the wards. Those who have appointed these duties must have done so in ignorance of the requirements of the sick; the nurse may be wanted in two places at once, but of course an inmate can nurse the sick or deliver the parturient woman whilst the nurse is weighing out dumplings. We said there is no night nurse, and what that means to the inmates can be arrived at only by making a survey of the patients in bed at the time of our visit.

Among the women there was a case of hæmoptoe complicating rheumatic neuralgia, a case of fibrous tumour lately operated on, another whose leg had been broken, now united, suffering with varicose veins, hemiplegia, swelled legs, paralysis, and the ordinary cases of infirmity and old age. On the men's side there was a bad case of anemia, a case of emaciation, who looked as if he needed scientific feeding by night as well as day, a man suffering from pressure on the veins of the legs, he was up; the cases on the male side not being so severe at the present time.

We found, to attend upon these people at night, on the female side, a young woman suffering from skin affection; that is to say, she slept in the ward, and was expected to rise when any attention was needed. We asked the nurse in what state she found her wards when she came on duty; her silence, accompanied with an expressive look, warned us that we had better not inquire further. On the male side there is an ancient pauper who attends on the sick during the night in the same way. We inquired whether the nurses were called in the night, and were told that these inmates were very careful in calling them when they were wanted. The nurse on the women's side is untrained, but she has had experience in workhouse nursing. On the men's side the nurse has been trained; she has been a long time in the work.

There were two women recently confined in the lying-in ward; there is no labour bed, nor did we see any screens or means to secure privacy in a small room. There is a separate lavatory for this ward placed alongside of it.

THE NURSERY

is a miserable little room on the ground floor; the door that gives access to it opens directly off a court, and has no screen or porch to break the draught; it faces another door, and to the left hand is the fireplace. Here we found six or more infants in the care of an old pauper assisted by one or two younger women. There is no proper lavatory attached to this ward, nor any bathing accommodation other than a movable bath. A few commode chairs were standing in a recess behind the door. The infants themselves were a sorry, sickly lot, evidencing that they do not receive skilled care or attention. There were no toys, but then that hardly mattered, for there was no space for play. The appearance of the children reminded one of the slum children in our London courts; they looked as if they and the gorgeous sun then flooding the garden had little to say to each other. It is a great pity that these infants are denied a fair start in life; no one seemed to understand them. The nurse on the female side is supposed to be responsible for them, but her duties are so manifold that she can give but a small fraction of attention to each. The infants leave the nursery at the early age of 2 years. At first we were prepared to regret that they were sent into the schools so young; but doubtless it is wise to transfer them to more sympathetic surroundings. At night the infants are with their mothers.

THE DINNER

was being served in the wards at the time of our visit. Some patients were having rice pudding; this was nicely cooked. The woman with hæmoptysis had a mug of hot beef-tea beside her, standing in close proximity to a spittoon into which she had been vomiting blood. At the table we saw the old women served with portions of fat and bone, among which there were minute streaks of meat, and a few potatoes, many of which were bad. As we looked on, the thought crossed our mind, Where are some of those fine vegetables that we saw in the garden? The rations are cut up in the kitchen and sent on open wooden trays to the wards. In the male ward the dinner was finished, and a pauper was washing the plates in a bucket of water placed on a chair—a primitive arrangement indicating that there is no wash-up sink.

THE SANITARY ARRANGEMENTS

are of a makeshift character. On the female side a slice at the end of the ward has been partitioned off, wherein is a bath with hot and cold supply, a sink, and, enclosed in a corner, the water-closet, having a flush and ventilated by a window. The whole of these appliances struck us as being in too close proximity to the ward to be sanitary. This lavatory, which was taken off the ward with 13 beds, served for the old women in the adjoining ward, and was supplemented by commodes beside the beds. The same arrangement was on the second floor with the exception of the lying-in ward. On the male side the sanitary appliances are worse. The closet is at the end of a dark passage; there is a movable bath, but no means of emptying vessels or slops but in the closet. The authorities admit that this is all very faulty, but we failed to gather that any improved system was in contemplation.

THE IMPRESSION

that we carried away was that the Bedford guardians are possessed of ample resources in the way of building and of space for the treatment of the sick and the rearing of the infants, but that for some cause or other neither of these results was accomplished. The sick are not nursed in the full sense of the word; by that we mean that there did not appear to be any energy in the carrying out of treatment ordered; but then how can it be otherwise when the patients are only nursed for twelve out of the twenty-four hours that go to make a hospital day, and when this duty is entrusted to women who have more patients to look after than they can nurse, whose patients, moreover, are scattered, and whose range of duty include many offices that of necessity take them away from their wards?

As for the infants, the less said about them the better; they are no credit, and they represent a grievous waste of opportunity, and therefore of public money. Again we say, Why are the old people not out in their own grounds? As we walked up the drive about 11 A.M. on that glorious June morning there were no inmates abroad but those who were working in the garden; we saw no seats, no pleasantly-planned corners for the old men or women, and as there are no dayrooms there is the more need for the change which going out of doors gives the paupers. What means is there of getting them down from the wards into the garden? Are they welcome when they get there? Does it never strike the guardians as they walk to and fro that to the old inmates, most of whom have been accustomed to entire freedom of going and coming, this is neither more nor less than a prison. We make these remarks in no captious spirit, but it would be a poor return to the guardians for their kindness in allowing us to see over the house if we did not try, in a friendly manner, to bring out those points which struck us, and into which they, as busy men and women, have not leisure to investigate for themselves. We are sure that they have the good of these poor people as much at heart as we have, and when they have grasped the fact that their lot might be improved by attention to detail, they will not rest satisfied until these matters are looked into.

DR. J. WRIGHT GRANT, public vaccinator for the Woburn Union has been granted the Government grant for successful vaccination.

DR. J. S. BROOKFIELD, of Brandonbury, has been placed on the Commission of the Peace for the county of Middlesex.

THE COST OF AN EPIDEMIC.

As an illustration of the pecuniary loss to the community arising through the prevalence of infectious diseases, Dr. Campbell Munro, medical officer of health of the county of Renfrew, in his annual report makes the following interesting statement: In the course of an epidemic of enteric fever in 1893 there occurred 859 cases, and 74 people lost their lives. He put aside any reference with respect to the immense amount of bodily pain and suffering, the mental distress and anguish, the misery and wretchedness involved in these figures. He confined himself to the pecuniary aspect of the question. Having before him an approximate statement of the wages earned by each individual wage earner attacked in the course of the epidemic, together with the average period during which he was prevented by illness from pursuing his occupation, he was in a position to estimate the cost of the epidemic to the community through loss of wages at £3,291. There was next to be considered the expense involved in connection with the treatment of these illnesses, extending, on an average, over seven weeks. He found that the average cost of treatment for each patient received into hospital in the course of the epidemic was about £3 15s. He was, therefore, well within the mark in estimating the average cost of treatment of cases, overhead, at £5. It might be taken that, in respect of a large proportion of the cases treated at home, the cost of treatment was limited by the pecuniary capacity of the household. The cost of treatment upon this scale amounted to £4,235. 35 was the accepted estimate of the average amount incurred in connection with funeral expenses, and the expenditure arising in this connection falls to be set down at £270. Finally, they had to estimate the value to the community of the lives lost in the course of the epidemic. That human life had a distinct pecuniary value was a consideration which had probably never entered the mind of the average citizen. Nevertheless, the matter was one susceptible of actuarial demonstration. A quotation from the writings of Farr, the greatest authority on the subject, would best illustrate the position of the matter: "As lands, houses, railways, and the other categories in the income tax schedules are of value, because they yield annual returns, so, for the same reason and on the same principle, the income of the population derived from pay of every kind, for professional or other services, and wages, can be capitalised; not precisely, it is true, unless the income of every person living were returned at least as nearly as incomes subject to income tax; but sufficiently near to the true value to show that the value of the population itself is the most important factor in the wealth of the country. The capitalisation of personal incomes proceeds upon the determination of the present value, at any rate, of the future annual earnings at that and all future ages."

The value to the community of an individual member was ascertained by deducting the capitalised future cost of subsistence of the individual from his capitalised future income. Proceeding upon these lines Farr arrived at the conclusion that "the minimum value of the population of the United Kingdom—men, women, and children—was £159 a head; that was the value inherent in them as a productive money-earning race." He estimated the value of the population of the United Kingdom at the time he was writing as equivalent to a capital sum of £5,250,000,000, while the "capital" of the country (using the term in its ordinary sense) amounted, according to Mr. Giffen's estimate, to £8,500,000,000.

Adopting Farr's figures as a basis for the calculation, he had made a rough estimate of the value "inherent in" the persons who died in the course of this epidemic, "as a productive money-earning race." He found that it amounted to the very large sum of £13,540. So that the pecuniary loss to the community of Mid-Renfrewshire, arising in connection with the epidemic, amounted to the enormous total of £21,496. A consideration of these figures, Dr. Munro observes, might well suggest the reflection whether any investment was calculated to yield a better pecuniary return than the expenditure involved in the operations of the Public Health Department, which had for their main object the prevention of epidemics.

BRITISH MEDICAL ASSOCIATION. SUBSCRIPTIONS FOR 1895

Subscriptions to the Association for 1895 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office Orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, JULY 13TH, 1895.

THE USE OF MEDICAL TITLES AFTER ERASURE FROM THE "REGISTER."

THE prosecution by the General Medical Council of Mr. Thomas Richard Allinson has been successful. We cannot conceive how it could have been otherwise. The result of the trial should stimulate the General Medical Council not only to institute proceedings in similar cases, but to obtain increased powers from the Legislature for dealing with what is a flagrant evil.

Mr. Allinson held the title of L.R.C.P. Edin. His name was erased from the *Medical Register* by the General Medical Council, and he was deprived of his title by the College of Physicians of Edinburgh. He appealed from the decision of the General Medical Council both to the Queen's Bench Division and to the Court of Appeal, but failed on both occasions. Having done so, he continued to use the title, and for doing this he has been subjected by the magistrate to the penalty of £20 imposed by the 40th Section of the Medical Act of 1858, and to the costs of the prosecution.

That a person should be at liberty still to use a title of which he has been legally deprived would indeed be a startling anomaly, nor is it possible to find a case more fitly covered by the words of the 40th section, which enacts that: "Any person who shall wilfully and falsely pretend to be or take or use the name or title of a physician. . . or any name title addition or description implying that he is registered under this Act or that he is recognized by law as a physician etc. shall upon a summary conviction for any such offence pay a sum not exceeding £20." But will the profession remain satisfied without a further step being taken in the direction of medical reform?

Erasure from the *Register* prevents a person from recovering his fees in a court of law; and the assumption of a title which has been taken from him subjects him to a penalty of £20; but neither prevents him from continuing to practise. Not one medical man in a thousand has to sue for his fees, and the public never inquire what a man's titles are or how he obtained them. That, for example, it should be possible for a person who has been convicted of felony and undergone penal servitude to continue to practise at all is surely a very grievous state of things. What is impossible in the legal profession should be equally impossible in the medical. A solicitor struck off the rolls cannot practise at all. The Inland Revenue and the Incorporated Law Society secure that result by the penalties they are able to obtain for his practising without a certificate. Antecedent, how-

ever, to some such protection being afforded to the public against medical men struck off the *Register* must be introduced a procedure analogous to that which for minor offences allows a solicitor to be punished by suspension for a limited period.

Under the Medical Act of 1858 there is nothing short of erasure with power to restore (a cumbersome process), and the result is at present to make no distinction between cases where a restoration should properly be allowed and where it should not be. Every day brings some fresh evidence indicating the necessity for a reform of the General Medical Council and its procedure. This is, in our opinion, one of the burning questions of the hour in the medical profession, and the sooner it is dealt with the better.

At the recent session, Sir R. Quain stated that the investigation of one case of alleged infamous conduct in a professional respect had cost hundreds of pounds. This investigation represented a large share of the work of the session. Notwithstanding this startling expenditure, even in cases where the Council strikes the name off the *Register*, they cannot compel the bodies granting the original qualification to remove the name from their list of licentiates, and the universities are (as is well known) unable or unwilling to cancel their degrees in such a case. Permanent erasure from the *Register* should only be allowed where the offence does not admit of subsequent restoration, and erasure from the *Medical Register* should automatically operate on the lists of the licensing body which gave the qualification to the person whose name is struck off. In future the power to practise (irrespective of fees and titles) should be prevented by the enforcement of penalties similar to those which can be recovered from the solicitor who has been struck off the Rolls as unworthy to continue a member of an honourable profession.

IMPENDING LEGISLATION FOR INEBRIATES.

NOTWITHSTANDING that the overturn of the late Ministry cut short the life of the thoroughgoing and effective Inebriates Bill, 1895, which, under the guidance of Lord Herschell, had passed a second reading in the House of Lords, no friend of legislative reform for the curative treatment of habitual drunkards need feel discouraged. In any circumstances this Bill could not have passed both Houses of Parliament before another session, so that the prospect of its enactment is no more remote than before the dissolution. There has been this advantage, too, that the drastic proposals in the Bill have been subjected to a searching criticism at the hands of the present Prime Minister and of several of the highest legal authorities in the kingdom. The late Government merit the highest praise for the main provisions of their measure, which embodied the chief points that have for many years been urged by the British Medical Association, the Society for the Study of Inebriety, magistrates, reformatory and prison officials, with other influential bodies and persons throughout the kingdom.

It was satisfactory to find that in the debate on the second reading in the House of Lords there appears to have been a general approval of one of the two great divisions of the Bill. No opinion was expressed against the curative treatment of inebriate offenders against the law, so there seems to be warrant for the anticipation of a new and more successful procedure with police-court inebriate "repeaters."

and other offenders who are habitual drunkards. As we have repeatedly shown, our mode of dealing with such cases by fine and imprisonment neither reforms nor deters, and is a ridiculous failure. We may, therefore, reasonably look forward to that therapeutic treatment of inebriate criminals which has been strongly recommended by the Parliamentary Committee of 1872, by three recent Departmental Committees (the English and Scotch Committees on Inebriates and the Committee on Prisons), and by the recent Canadian Royal Commission on Intoxicants. This part of the now defunct Bill, with whatever alteration of details may be deemed desirable, will probably be brought forward again by the Cabinet, to several members of which we were considerably indebted for the Acts of 1879 and 1888.

Exception was taken, however, to the other great division of the Bill of the late Government—that embodying compulsory curative detention of habitual drunkards not charged with any offence against the law. It was objected that the liberty of a person who had not been charged with committing a legal offence was proposed to be placed at the discretion of a judge. The noble lords who so strongly condemned such a provision as a new and unheard-of infringement of individual liberty, appear to have forgotten that the liberty of a person not charged with a legal offence has already so been curtailed in alleged lunacy. Every year a large number of individuals who have not been charged with the commission of any offence are deprived of their liberty and put under restraint at the discretion, in non-pauper cases, of two justices, and in pauper cases of one justice. It is not a crime to be insane, yet in the interests of the non-criminal presumed mentally unsound, hundreds of innocent individuals, guiltless of any legal offence, are compulsorily secluded by two justices, one metropolitan stipendiary, or one justice. This old cry of "the liberty of the subject" has really no proper application to the habitual drunkard, who is an abject slave and involuntarily abuses his legal liberty to the destruction of the liberty of other persons.

We presume that Lord Ashbourne has been incorrectly reported when he is stated to have said that all habitual drunkards are already provided for by having an opportunity of voluntarily entering retreats. No provision has been made for the poor and for persons of limited resources, so that only a small proportion of habitual drunkards, especially of the male sex, have now the opportunity of placing themselves under therapeutic detention. Even if there were provision for the impecunious and destitute, the greater number of inebriates have become too will-paralysed to apply for curative seclusion of their own accord.

The objection urged by the Lord Chancellor that a serious temptation might be placed in the way of people with rich inebriate relatives would, if tenable, be equally fatal to our existing compulsory dealing with persons of unsound mind. Lord Salisbury's objection to vesting the power to sequester personal liberty in the discretion of a fallible judge applies as strongly to lunatics, and precautions can be taken to avert a miscarriage of justice.

These objections can all be fairly met by appropriate safeguards which we would heartily welcome. One safeguard suggested would, however, render compulsory procedure largely if not wholly inoperative. We mean the leaving of the decision in each case to a jury. Inebriates and their friends usually shun publicity, and it would be difficult to

persuade either to bring their troubles before the public. But if a jury be insisted on, even then we urge the great importance of the enactment of compulsion. We believe, however, that individual liberty would best be protected by a close definition of habitual drunkenness, by ample power of appeal, and by frequent Government or other inspection. With Commissioners of Inebriety as now of Lunacy, complete security and supervision could be attained, and a dangerous class of helpless diseased inebriates, who are now a terror at once to their friends and to the community, could be cared for, and in considerable proportion cured.

CAMBRIDGE "SUMMER SCHOOL."

DURING the first week of July a novel experiment was tried in the University of Cambridge. It appeared to the professors and teachers of the University that many medical men too deeply engaged in practice, as is the case with most medical men, to be able to keep pace with the recent advances in the ancillary sciences would be glad of an opportunity of renewing their knowledge, and of seeing for themselves those newer methods and discoveries in physiology, pathology, and bacteriology which are changing the face of modern medicine. We may read about these things in journals, but after a time the reader, busy in other ways, begins to find himself distanced in the race; indeed, the very language of physiologists and pathologists gradually ceases to have any meaning for him. This is the greater misfortune as these very same men do not lose their interest in the scientific side of medicine; on the contrary, their daily experience convinces them more and more of the importance of it. To give the busy practitioner an insight into these new methods and new results was the object of the Summer [School] at Cambridge, and a week of very hard work was got through. About eighty medical men came into residence, and were accommodated for the most part in King's and Downing Colleges. The visitors were mature, thoughtful men of large experience, who followed the somewhat severe course laid out for them with an assiduous and even enthusiastic interest.

A great debt of gratitude is due to the professors and lecturers who, at the close of the hard work of term, were willing to postpone a well-earned holiday and to prepare lectures and demonstrations of no perfunctory kind. Some of the demonstrations indeed were of a very elaborate and complete kind, and must have needed many hours of preparation.

The fees charged were barely sufficient to cover the cost of board and lodging and the necessary printing and other immediate expenses of management.

The effort has had the reward of signal success. We hear from the visitors that they were intensely interested in all that they saw, and they express in the strongest terms their sense of the value the "school" has been to them, and their admiration of the thoroughness and variety of the work done in the several laboratories of the University and in the hospital. On the other hand we learn that the teachers on their part were much encouraged by the close attention and intelligent interest taken by their new pupils in the subjects which were brought before them.

A very strong desire was expressed both by those who were present, and by those who would have been present if they

could, that the University may be induced at no distant date to repeat the demonstrations.

The post-graduate courses given in London are carried out on a different plan, and with a different purpose; they are not occasional demonstrations of special subjects but systematic courses of instruction which the Cambridge Summer School does not pretend to give.

LEPROSY AT THE CAPE.

THE final report of the Cape Leprosy Commission has recently been presented to the Cape Parliament. According to the census of 1891 the total number of lepers in the colony, including Griqualand West and the native territories, was 625, or 4.77 per 10,000 of the population, and of these 366 were males and 259 females. Fifty-one of the cases were European or white, and of the remaining 574, 532 were born in the colony, 41 in external Colonial Africa, and one in Asia. Of the 51 white lepers, only 4 were born out of the colony, and these had become diseased after their arrival in South Africa. The disease was most common among the Hottentots, the mixed races showing the next largest proportion, then the Malays and the Fingoes, and lastly the Kaffirs and Europeans. In January, 1895, the total number of colonial lepers officially known was 1,177, but it is believed that there are still more. The disease is thus showing a steady increase among the native races, as it is also among the whites.

With reference to the communicability of leprosy the Commission point out that, admitting as the most probable theory its spread by contagion, the chances of becoming inoculated are greater in the family circle, especially in South Africa, where family ties are strong, the close intercourse of relatives the prevalent custom, and hygienic precautions are to a great extent neglected. Living in crowded numbers in small houses, occupying the same bed, using the same utensils, dirty habits, etc., and the general belief that leprosy is a "visitation of God," all tend to the spread of the disease by contagion, and thus to a great extent may be explained the fact that leprosy runs in families. The theory of the communicability of the disease appears to be the only one which can satisfactorily clear up every point in connection with the gradual spread and gradual decrease at different epochs.

As regards the promulgation of leprosy by vaccination, no single instance was met with or brought forward where it was asserted that leprosy was caused by vaccination, and no distinct evidence could be adduced to show that it could be so caused. From the official returns the proportion of lepers per 10,000 was 1.35 for Europeans, 5.04 for Malays. Now the latter, being Mohammedans, do not submit readily to vaccination, and a large number of them are unvaccinated. Moreover, the proportion of lepers among the Hottentots and Fingoes in the native territories, where vaccination is only sporadic and partial, is much greater than it is among those at the Cape, where vaccination has been practised for a longer period and much more thoroughly. Leprosy, indeed, is least prevalent among the most vaccinated people—the whites—and most among the least vaccinated—that is the native and other races of the native territories. It is also pointed out that when arm-to-arm vaccination is practised the lymph is taken from healthy infants. For prac-

tical purposes, therefore, there cannot be the least fear that leprosy is likely to spread by means of arm-to-arm vaccination, even in the hands of careless and inexperienced vaccinators.

The Commissioners have come to the conclusion that there is no proof of the direct hereditary transmission of leprosy, and are further of opinion that a hereditary predisposition can be adduced, if at all, only in a very small number of cases.

As regards the marriage of lepers, the report shows that leprosy does not produce sterility in all cases. Conjugal intercourse therefore should not be permitted between the leprosy and the healthy, and only after the child-bearing age is passed, when both husband and wife are affected.

A careful inquiry was instituted by the Commissioners into the alleged cures spontaneously or by treatment. Of 72 such cases only 6 could be looked upon as having the disease arrested. For practical purposes the Commissioners consider that when a case of anæsthetic leprosy has remained inactive for two years it may be regarded as one of "temporary arrest," and that when no fresh symptoms appear for a further period of three years it may be looked upon as permanently arrested. They are of opinion that the former class may be entitled to their liberty under certain conditions.

The Commissioners have come to the conclusion that all the recommended remedies for leprosy are of no avail, and that leprosy is an incurable disease so far as medicinal treatment is regarded.

The report strongly urges a modified system of segregation. There should be compulsory notification in every case of leprosy by the householder or occupier and by the attending medical practitioner. The isolation should be effected either in asylums, licensed houses, private dwellings, or in leper villages or locations. An asylum should at once be provided on the mainland in the western district, and another subsequently in the eastern district. The asylum of Robben Island should be temporarily maintained for the pauper class and for those unable to comply with the regulation as to isolation in their own homes. Those should also be sent to Robben Island who do not conform to the regulations.

MR. JOHN LINTAIGER has been elected, without opposition, to fill the seat on the Council of the Royal College of Surgeons (Ireland) vacant by the death of Sir George Porter.

ON the occasion of the marriage of the Duke of Aosta, the King of Italy conferred on Dr. Vintras, senior physician to the French Hospital, and physician to the Italian Embassy, the Order of St. Maurice and St. Lazare (Officer), for the services he has rendered to the poorer members of the Italian colony in London.

DURING the annual meeting of the British Medical Association in London, the President and Fellows of the Obstetrical Society of London intend to give a banquet to distinguished foreign obstetricians and gynaecologists. The entertainment will take place at the Whitehall Rooms, on Friday, August 2nd, at 7 P.M.

CAMBRIDGE MEDICAL GRADUATES' CLUB.

THE annual general meeting and dinner of this Club was held on July 4th at the Hotel Victoria. The President of the Club, Sir George Humphry, M.D., F.R.S., was in the

chair and after the usual loyal toasts proposed "The Health of the Club." Dr. Norman Moore gave the toast of "The Guests of the Club," to which the Rev. Canon W. Page Roberts, Mr. O. Pemberton, and Mr. T. Fridgin Teale, F.R.S., responded. Prof. C. S. Sherrington proposed "The Health of the Chairman," Sir G. M. Humphry.

SURGEONCY TO THE QUEEN IN IRELAND.

SIR PHILIP SMYLY has been appointed Surgeon to the Queen in Ireland, in room of the late Sir George H. Porter, Bart. He is Surgeon to the Meath Hospital, and has served as surgeon to various viceroys. Some years ago he resigned his position as Surgeon to take that of Physician to the Lord Lieutenant of the day.

WHAT IS A HABITUAL DRUNKARD?

THE daily journals report the presentation of a petition to the House of Lords, praying that any person who has been twice convicted of drunkenness within two years in the same licensing district shall be defined to be a habitual drunkard, and that any licensed dealer serving or harbouring him after due notice shall be liable to penalties and forfeiture of licence. So severe a measure will, we feel assured, never be enacted by any civilised Legislature. In existing legislation three convictions within six months—as in South Australia—constitute an inebriate a "habitual drunkard;" but twice in two years is utterly irrational. The late Government's Inebriates Bill proposed three convictions within twelve months, but the too drastic character of this definition would have been altered if the Bill had gone on. The object of the petition is excellent, though the operation of the Bill could be effectual only in small communities, where the inhabitants would know such cases.

THE DIFFICULTIES OF MEMORISING.

"Sir," once said a black house-boy at a Chicago Hotel to a distinguished English doctor, "can you give me anything to help me to memorise? You see, sir, if I could only memorise orders I could get a place in the restaurant; but my memory is so short that by the time I have got to the kitchen I have forgotten the order." Alas for this dusky applicant and for others with short memories, no medicine has yet been discovered to enable one to memorise. We can help our patients to forget, we can, by the aid of drugs, give them for a short time a bath in the waters of Lethe; but, as every student knows who labours at his *memoria technica*, medicine will not help him to remember. In illustration of the difficulties some people find in remembering the small details of daily life an amusing story is told of Walter Savage Landor. He was extremely forgetful and was apt to arrive at a friend's without the keys of his portmanteau. Starting once on a journey he determined not to forget his keys. He carefully placed them in his pocket, and took them out several times during the journey to make sure they were there. On arriving at his journey's end he produced the keys with pride; but his treacherous memory had again played him a trick, for this time he had forgotten his portmanteau.

THE COUNTY MEDICAL OFFICER FOR ESSEX.

FOR some years past Dr. Thresh has been medical officer of health for two large rural districts in Essex—Maldon and Chelmsford—and has achieved a remarkable record of important sanitary work under circumstances of no small difficulty. He has also been engaged by the Essex County Council to advise them in various matters, including the collating of annual reports, but without formal and permanent appointment under the Local Government Act. This omission has now been rectified, and all who are interested in the public health of the county will learn with satisfaction that the Essex council have decided to fall into line

with the pioneer counties, of which mention has often been made in the *BRITISH MEDICAL JOURNAL*. They have appointed Dr. Thresh as county medical officer, but without depriving the Chelmsford and Maldon districts of his services. The list grows slowly, but this latest addition is most welcome and encouraging from every point of view. The county council could not have made a better choice, nor could Dr. Thresh have found a more fitting field for the wider application of the skill and knowledge, which have already borne such good fruit in a portion of the county.

EDINBURGH NEW CITY HOSPITAL FOR INFECTIOUS DISEASE.

AT last, after endless consideration, after consulting with the Royal College of Physicians, after taking advice here and there, after looking at this property and that, after thinking about it for years, the Town Council of Edinburgh at its meeting on Tuesday last suspended its standing orders to permit of remitting to the Public Health Committee the question of considering the suitability of the grounds adjoining Craiglockhart Poorhouse, and belonging to the City Parish Council, as a site for the new city hospital, with powers to consult experts, and if so advised to conclude arrangements for a sufficient part of the ground for their purpose.

NEW KNIGHTS.

WE announced briefly in the *BRITISH MEDICAL JOURNAL* of July 6th that the honour of knighthood had been conferred on Mr. Thornley Stoker and Dr. Christopher Nixon, of Dublin. Sir Thornley Stoker is President of the Royal College of Surgeons, Ireland, having been elected a second time to that office. He was educated at the school of the College of Surgeons, and at Queen's College, Galway, and St. Vincent's Hospital, Dublin. Having graduated M.D. in the Queen's University (1866), he became a Demonstrator of Anatomy in the College of Surgeons, and was soon after appointed a surgeon to the City of Dublin Hospital. In 1873 he was elected to the surgical staff of the Richmond, Whitworth, and Hardwicke Hospitals, and later on he became Professor of Anatomy in the Royal College of Surgeons, an office which he held for several years. He is also Fellow and Examiner in Surgery in the Royal University, Surgeon to Swift's Hospital for Lunatics, and Professor of Anatomy and Hon. Academician of the Royal Hibernian Academy. He has written much on surgical subjects, and he is well known as a skilful surgeon. Sir Christopher Nixon, who was knighted on the same occasion, is Senior Physician to the Mater Misericordiae Hospital. He was educated at the Catholic University School. In 1869 he became a Licentiate of the College of Physicians, and he was elected to the Fellowship in 1876. Having entered Trinity College he graduated M.B. in 1878. He also holds the degree of LL.D. in the University of Dublin. When the Royal University was founded he was made one of the Fellows and an examiner in medicine; these offices he resigned on being appointed a member of the Senate. He holds the degree of M.D. (*hon. causa*) from that University. He is Visiting Physician to the Central Criminal Lunatic Asylum, Dundrum, and Professor of Medicine in the Catholic University Medical School. He has contributed a good deal to the literature of his profession, in which in Dublin he holds a prominent position.

ROCHFORD WORKHOUSE SCANDAL.

THE epidemic of scandals relating to the administration of the Poor Law has now broken out in Essex. A Local Government Board inquiry, reported fully in the *Essex Evening News* of June 22nd, has lately been held at Rochford, as to certain allegations made by the guardians against the master of the workhouse, whom they had suspended from duty. It appeared that in 1890 a difficulty arose on the question of drink,

when the master was requested to resign by resolution of the guardians, but the resolution was withdrawn upon his signifying a pledge of total abstinence. The guardians, in consequence of a large amount of evidence leading them to believe that he had not only broken his pledge of total abstinence, but had, in point of fact, been frequently and disgracefully drunk, had again invited him to resign; but they told the inspector that he had "set them at defiance." The case, as it was detailed before the inspector, presented all the usual phenomena. There was the usual anti-reform party on the guardians, who were prepared to stick to the master through thick and thin. There were those among the officers who were cordially prepared to back him up. There were others who appeared to know more than they cared to say, being, doubtless, of a cautious mind. The master denies the whole of the evidence deliberately, and the matron, who is his wife, gave evidence in his favour. In addition, the solicitor who conducted the case for the master brought up a whole body of the tradesmen of Rochford, who protested that they had known the master for years and years, and had never seen him the worse for drink. The Local Government Inspector, Mr. H. Preston Thomas, is now, we presume, deliberating upon the evidence, and in due time we shall hear what view he and his new chiefs take of this and the other pending cases. Without attempting to prejudge the allegations against this particular master, we feel bound to say that the accumulation of these cases is destroying public confidence in the administration of the Poor Law, and that it is high time that the Board dealt seriously with the reform of the Poor-law administration, upon which the happiness of so many thousands of helpless and poor people constantly depends.

TESTIMONIAL TO SIR JOSEPH LISTER.

SIR JOSEPH LISTER will on July 30th be presented with his portrait, painted by Mr. J. H. Lorimer, A.R.S.A., at a meeting to be held at 4 P.M. on that day at King's College Hospital. The presentation will be made by Sir John E. Ericsson, President of University College. When Sir Joseph Lister retired from active hospital and teaching work last year, it was felt that the occasion ought not to be allowed to pass without showing in some tangible way the regard and esteem in which he is held by his former colleagues and pupils. The Honorary Secretary of the testimonial fund is Dr. J. Frederick W. Silk (29, Weymouth Street, Portland Place, W.), to whom applications for admission to the ceremonial should be addressed.

PROPOSED MEMORIAL TO PROFESSOR HUXLEY.

It has been decided to establish, in connection with the Charing Cross Hospital Medical School, a permanent memorial to one of its most distinguished students, the late Professor Huxley. To this end the following Committee has been formed: Sir Joseph Fayrer, K.C.S.I., F.R.S., Sir Guyer Hunter, K.O.M.G. (both old friends and fellow students of Professor Huxley at the Charing Cross Hospital); Dr. Watt Black (Honorary Treasurer), Mr. J. H. Morgan, Mr. Stanley Boyd, Dr. Montague Murray, and Mr. H. F. Waterhouse (Honorary Secretary). It is proposed that the memorial shall take the form of an annual lecture and a science scholarship and medal. A meeting to consider the matter will be held at the School, on Tuesday, July 12th, at 3 P.M., under the chairmanship of Sir Joseph Fayrer. Subscriptions will be received by Dr. Watt Black at the Charing Cross Hospital Medical School. Sir W. H. Flower, writing to the *Times*, says: "In the great hall of our National Museum of Natural History the noble statue of Darwin will hand down to posterity the image of the man as he appeared to all who knew him in life. Near this will soon be placed another statue remarkable for the accuracy with which the striking personality of Owen is represented, as all can testify. Surely this group

of the great naturalists of this country and this century must be completed by the one which we have just lost, in some respects the greatest of the three. The statues of Pitt and Fox stand side by side in Westminster Abbey. Huxley and Owen, often divided in their lives, would here come together after death in the most appropriate place, and amid the most appropriate surroundings. I should have waited before venturing to launch such a suggestion in public until it had been considered by a properly chosen and representative committee, but that I see other memorial projects have already been widely circulated."

THE HIGH DEATH-RATE OF BELFAST.

A CORRESPONDENCE is going on in the Belfast papers regarding the high death-rate prevailing in that city. The rate for last week was 27.7. This is, however, considerably above the average. Nevertheless, the normal rate, which is about 24 or 25 per 1,000, is considerably too high. The causes of this are many, and some of them are undoubtedly remediable. The damp subsoil on which the city rests, and the fact that a very large proportion of the population are engaged in unhealthy trades, are causes always in operation, but up to the present the drainage and water supply have not been altogether satisfactory. Energetic steps are, however, being taken to remedy these defects. The large main drainage scheme is almost completed, and the new water scheme for bringing a supply from the Mourne Mountains is being pushed on rapidly. In estimating the significance of the high death-rate of Belfast, it should not be forgotten that the city is advancing in population with astonishing rapidity, and that this exceptional increase is fraught with various dangers to the public health.

THE MECCA PILGRIMAGE.

DR. D. H. ATTFIELD, M.A. Cantab., English Quarantine Medical Officer of the Egyptian Government at Suez, who last year, during the Mecca pilgrimage months, filled the post of Sub-Director of the Quarantine Camp at El Tor, has this year, during the similar period, been appointed the Chief Director of the extra Egyptian Camp at Ikingi Matruh. Dr. Attfield is the son of Dr. J. Attfield, F.R.S., whose services in connection with the editing of the *British Pharmacopœia* are well known.

ON DISGUIISING THE TRUTH.

IN another column we print a letter from a lay correspondent, which raises an important point of medical ethics. J. H. T. alleges that medical men are in the habit of concealing the truth from patients in whom they find evidence of serious disease. For a statement of his case we refer to the letter itself, in which our correspondent puts forth one aspect of the matter ably and clearly, and with fairness and moderation. Our own reply is a simple one—namely, that on the whole we agree with him. In each case there are found its own difficulties for which no general rule can be laid down, but we do not hesitate to say that, taking the cases related by J. H. T. in the unqualified way in which they are recorded, the medical men concerned acted very wrongly. We do not believe for a moment that medical men practise the habitual deceit which is attributed to them by J. H. T. That any physician should conceal the state of his patient from his family and confide it to a nurse seems to us inconceivable. A nurse has nothing to do with the diagnosis of her patient's disease, but with obedience to orders only. A nurse who has a becoming aversion to gossip will indeed prefer to avoid all unnecessary confidences; while those who are gossips must be deprived of the means of mischief. It must be remembered that some patients—and these not a few—are averse from being told the truth with whatsoever tact it may be conveyed; to force a painful truth upon such persons would be both unkind and mischievous. We believe that in all such cases physicians are

accustomed to convey the facts to some responsible member of the family, with whom the decision then lies, and a physician who fails to do this is, in our opinion, worthy of blame. It is incredible to us that any physician should detect epilepsy in a patient and fail to take the fullest care to warn his friends and provide for his security. To blurt out within the limits of an ordinary morning consultation so painful a discovery, and this to a patient who may be a perfect stranger, would be most inconsiderate; and when such discoveries are made in persons who call alone and unknown, the course to take is not always plain, but the course of absolute silence can never be right. When a person having already some forebodings of evil asks the physician to tell him the truth, it is the custom of all experienced medical men to tell the truth gently but clearly, tempering the communication with such allusions to any aspects of doubt and the fallibility of human prediction as may alleviate the hardness of the sentence. We remember one case only in which a deliberate untruth was told at the bedside; this was in the case of a very nervous and wistful young man who was lying in the crisis of a desperate pneumonia, and it was felt that an assurance of recovery might help to promote it. The assurance was given after full consultation with the family and consideration of the patient's worldly and spiritual state. However, the "suggestion" failed, and the physician chiefly concerned has never satisfied himself whether he then did right or wrong. He is disposed to think that he was wrong.

"COVERING."

THE conduct of Dr. R. A. Lithgow, as brought out at the inquest last week on the body of Mrs. Scott-Campbell, in attending a patient in consultation with a man whose name has been erased from the *Medical Register*, and in subsequently giving a certificate of death, has been the subject of much comment in medical circles. Of recent years the General Medical Council has shown the utmost determination to deal severely with "covering" of unqualified practitioners by medical men; and though in the present instance the facts are a little different from the usual run of these cases, we have no doubt that the case is one that will be fully investigated by the General Medical Council. Dr. Joseph Kidd will doubtless be also given an opportunity by that body of explaining how it happens that he has held consultations with the same man, and as was alleged at the above-mentioned inquest, has signed a death certificate for him. Without in any way wishing to prejudge the case, we cannot refrain from asking of what avail it is to strike a man off the *Register* if medical men may help him out of the only dilemma which such a sentence entails.

CONVICTION UNDER THE REGISTRATION ACT, 1874.

MR. BRAXTON HICKS, Her Majesty's Coroner for London and Surrey, is to be congratulated for the public-spirited way in which he has again shown that the Registration Acts are not dead letters—in his district at least. On July 4th he summoned Mr. Coppin, an unqualified assistant to a medical man living in the Westminster Bridge Road, for wilfully and falsely giving a certificate of the cause of death contrary to the Registration of Births and Deaths Acts, 37 and 38 Victoria, cap. 88. It may be remembered that Mr. Braxton Hicks brought the qualified principal in this case before the General Medical Council at the last session for "covering," and that the Council, in its wisdom, although finding that the offence was committed, did not erase the name of the offender from the *Register*, but "ordered him to come up for judgment in November." Mr. Braxton Hicks, in opening the case against Mr. Coppin before Mr. Kennedy, the police magistrate, stated that he had taken out six summonses in all. He did not, however, want the case to go for trial, but if a conviction was obtained, that the case

should be dealt with summarily. Accordingly he withdrew five of the cases, and elected to deal with one only. The evidence was then produced, and there being practically no defence, the magistrate inflicted the full penalty of £10, with 2s. costs, and informed the defendant that he must consider himself very fortunate in not having the other charges pressed against him. Mr. Coppin, whose name will be remembered as having been mentioned before in connection with the Neil Cream case, has already brought other principals into professional difficulties whilst acting as their unqualified assistant. Why medical men should still continue to run such risks as the employment of unqualified assistants leads to is difficult to understand, especially when there are numbers of fully qualified and capable assistants to be obtained easily. Mr. Braxton Hicks has the courage of his convictions, and never loses an opportunity of seeing that the laws which regulate registration of deaths are carried out properly. He is a "terror to evil doers" in his district, and though not a member of the medical profession, has always the interest, honour, and dignity of that profession at heart.

SIGNS OF PROGRESS.

WE are much impressed, whilst reading the reports of the guardians' meetings all over the country, by the evidence of progress all along the line since we commenced the publication of our series of reports on provincial workhouse infirmaries. At Barnstable there is a lengthy discussion on providing improved and increased accommodation for the sick; at Basingstoke the need of a new infirmary is acknowledged, and a powerful majority on the Board are pledged to carry it through; at Elham the Board are building rooms for the night nurse; at Coventry a warm discussion on the need of a night nurse occupied the time of the Board, and though we are sorry to read that the stock arguments as to absence of complaints on the part of the inmates and the chronic nature of the cases carried the day, yet we quite expect to find the Coventry Board swept along on the tide of improved nursing which has evidently set in all over the country. Totnes is advertising for a trained and certificated nurse; and various other advertisements show activity among the workhouse infirmaries, which we hail as a proof that the local authorities are waking up to their duties.

PRESCRIPTIONS AND DISPENSERS.

A CASE of importance, raising the question of prescriptions, substitution, etc., was decided in the Edinburgh Sheriff Court, on June 17th, when Sheriff Rutherford heard proof in an action by David Middleton, chemist, 85, Bruntsfield Place, Edinburgh, against James M. Wilson and Co., chemists, 16, Leven Street, Edinburgh, and Patrick W. Wilson, chemist, the only known partner of the said company. Plaintiff sued for interdict against the defenders from dispensing prescriptions of the pursuer's special preparation known as "Middleton's Cod-Liver Oil Emulsion" by substituting for such emulsion some preparation of their own, and costs and damages. It was proved that the defenders had on several occasions substituted their own preparations for those ordered. It was shown that a chemist had no discretion in altering a prescription; he must conform strictly to what was ordered. If he has not the special preparation in stock he must send for it. There must be absolute honour between prescriber and dispenser. The Sheriff found that the defenders acted wrongfully in substituting a different preparation of cod-liver oil for the pursuer's emulsion, specially prescribed, and the defenders liable to the pursuer in expenses. In an appended explanatory note the Sheriff expressed the opinion that there could hardly be any room for doubt that a druggist or pharmacist is not entitled to deviate from the directions contained in the written prescription of a medical practitioner, but is bound to comply with them literally and implicitly.

It is to be hoped, our Edinburgh correspondent writes, that this decision will lead to greater care in making up prescriptions than prevails among some chemists. Physicians are sometimes annoyed by failing to get certain results from certain treatment and by discovering that inferior or different preparations had been substituted for those specifically ordered. Thus there are certain preparations of tincture of *strophanthus* known to be of excellent quality and some which are not so; or, again, when *infusum digitalis recens* is ordered, a chemist has no right to use a concentrated and preserved substitute.

"A DAY IN THE COUNTRY."

CANON BARNETT, whose genuine philanthropy is all the more effective that he has followed the advice of Johnson and cleared his mind of cant, calls attention to the many objectionable features of school treats as generally conducted. We are entirely at one with him in his outspoken condemnation of the whole thing as "an abuse of charity." Coming as it does from a quarter not open to the suspicion of what may be called sanitary pedantry, the protest is likely to have all the greater force. To the sentimentalist nothing can be more delightful than the idea of the pale little denizens of the slums escaping for a few hours from the unwholesome atmosphere in which they have their being into the sweet air and unconfined space of the country; when he reads the customary appeals in the papers, pictures of young lambs skipping in the meads and of happy children romping in the summer fields rise before his mind's eye, and he responds liberally. One need not, however, look at life through the spectacles of M. Zola to see a less idyllic picture. Vans and railway carriages crammed with seething masses of screaming, struggling children; little sons and daughters of Belial flown with insolence and bad ginger beer; a debauch of noise, guzzling, and excitement, followed by utter prostration from the combined effects of heat, fatigue, and indigestion—this is too often the reality of "a day in the country." The sentimentalist has his money's worth in the sense that he has made a slight rift in the dismal clouds which overhang the lives of poor children, but what of the little ones themselves? At best they get nothing but a day of feverish excitement, and they are fortunate if they escape with nothing worse than hoarseness and exhaustion. It is hardly necessary to explain that it is not to the "day in the country" itself, but to the manner of it, that we object. Holding strongly as we do that, in the words of Herbert Spencer, "happiness is the best of tonics," we think it would be well if every town child could have, not one, but many days in the country, and we should be glad if Canon Barnett's suggestion that the little ones should be sent one by one to spend a fortnight in labourers' cottages could be carried into effect. This is already done to a certain extent for the poor children of Paris, and surely it is not altogether impossible of accomplishment here. A fortnight or even a week in the country would do much to purify the bodies and souls of children from the taint of the slums. The money subscribed for "a day in the country" would assuredly be much better bestowed in aiding such a movement.

AN INSANITARY AREA IN SOUTHWARK.

At a meeting of the Vestry of St. George Southwark on July 2nd a report was presented by the medical officer of health dealing with the mortality statistics of the area known as the Falcon Court area, which the London County Council and the vestry have determined to deal with by an improvement scheme under the Housing of the Working Classes Act. It appears that the area in question has a population of 707 persons, and that the actual space covered by dwelling houses is rather under 1½ acre, so that there is considerable overcrowding. The returns of mortality for the three years 1892-3-4 show an average death-rate of 20 per mille as compared with 19.8 for the whole of London. The death-rate

for the seven chief zymotic diseases is 4.4 per mille as against 2.5 in London, and the average deaths under 1 year of age to every thousand births number 208 in the area as against 151 in London. The medical officer of health comments upon the fact that his statistics are based upon a small area and population, and only deal with a period of three years; he very properly insists, therefore, upon the undesirability of attaching undue importance to his figures. He alludes, however, to the unsatisfactory nature of the results which have been obtained during the past three years by the service of notices upon owners and occupiers of property in the area, and states that the action taken has merely ended in the removal of a few of the grosser and more glaring defects; the faults of a structural nature, he states, are many in number and of a serious nature. This can only be remedied by carrying an improvement scheme into execution.

DIET IN PREGNANCY.

Dr. EICHHOLZ, of Kreuznach, in a recent number of the *Frauenarzt*, maintains that a large proportion of the discomforts and difficulties preceding, attending, and following parturition might be avoided by a rigid adherence to some simple dietetic rules. Excess of albumen and of water are, he considers, the errors against which pregnant women should be warned, as tending respectively to excessive development of the foetus and secretion of amniotic fluid. His rules are: Meat only once a-day, and that in small quantity, and rarely if ever salted; green vegetables, salad, potatoes, bread and butter, but avoiding as far as possible eggs, peas, and beans as being too rich in albumen. Thirst to be quenched by milk or water in very moderate quantities, and cocoa in preference to tea and coffee. Wine, beer, and spirits to be forbidden, and drink of any kind unless in case of urgent thirst; but fruit, raw or cooked, to be indulged in *ad libitum*. The general result of such a diet he found to be a remarkable feeling of well-being; the sense of fulness, bearing down, and weariness, thirst and constipation soon disappeared, and the patients have been able to walk many miles up to the eve of confinement. His own wife would leap ditches and climb hills, and even on one occasion ventured on a race for endurance. The ease and rapidity of the deliveries in some 25 consecutive cases, some of whom had previously had tedious or difficult labours, the small amount of liquor amnii, often not more than a teacupful and sometimes almost inappreciable, were striking, and all without exception succeeded in nursing their infants, though some had not been able to do so before. The children were healthy but small, mostly weighing 6 lbs., and the circumference of head was under 36 cm., averaging 33 to 34. The restriction of albuminous foods had no injurious effect on the quantity or quality of the milk.

THE MILK SUPPLY OF LONDON.

THE second report of the Special Commission on the milk supply of London will appear in the *BRITISH MEDICAL JOURNAL* of July 20th.

THE FORFARSHIRE MEDICAL ASSOCIATION.—The thirty-seventh annual meeting of this Association was held at Forfar on July 4th, Dr. Cable, President, in the chair. The financial statement showed that the Association was in a satisfactory condition. The following officers were elected:—*President*: Dr. Adam, Brechin. *Vice-President*: Dr. Johnston, Dundee; and Dr. Hunter, Forfar. *Council*: Drs. J. W. Miller, Simclair, Baist, Mackie Whyte, Mackay, Steel Mason. *Local Secretaries*: Drs. Kay (Montrose), Cable (Forfar), Laing (Aberbroath), Adam (Brechin). A donation of three guineas was voted to the British Medical Benevolent Fund. The President (Dr. Cable) delivered an address on Micro-organisms and Disease, for which he received the thanks of the meeting. The next meeting will be held at Edzell.

BRITISH MEDICAL ASSOCIATION.

SIXTY-THIRD ANNUAL MEETING OF THE
BRITISH MEDICAL ASSOCIATION
IN LONDON, 1895.

THE MEDICAL INSTITUTIONS OF LONDON.

(Continued from page 91.)

THE MEDICAL SOCIETIES OF LONDON.

By JAMES BLAKE BAILEY, B.A.,

Librarian of the Royal College of Surgeons.

THE ROYAL MEDICO-BOTANICAL SOCIETY OF LONDON

was founded in 1821 mainly by the efforts of John Frost, who held the office of Director. The avowed object of the Society was for "the purpose of investigating, by means of communications, lectures, and experiments, the medicinal properties, botanical characters, and chemical constituents of plants; for encouraging the study of the *materia medica* of all countries, etc." Frost was only 18 years of age when he started the Society, and by his perseverance and impudence he soon put it on a good basis. The home of the Society was at 32, Sackville Street, Piccadilly, and Dr. William G. Maton, F.R.S., was the first President. His successors were Dr. Bree, Sir James McGrigor, and Earl Stanhope. Frost obtained not only the chief men of science of his day as members of the Society, but also politicians and men of letters; it is said that he had twelve Sovereigns on the list of members. His mode of obtaining these names was to present an elaborate album containing the signatures of the members to any distinguished man whom he desired to catch, and to inform him that he had been elected an honorary member. By this means he not only increased his list of members, but put together a most interesting and valuable collection of autographs. At the disappearance of Frost after the quarrel between him and the Society, the book vanished, and has never since been heard of. This is to be regretted, as it contained signatures of great interest. Some of the subtleties to which Frost had recourse for getting his book signed are well-nigh incredible: Having more than once failed to get an audience with the Duke of Wellington, Frost obtained the uniform of a lieutenant-general, and attended a *levee* of general officers at Apsley House. By sheer impudence he obtained an audience, and added the Duke's signature to his list. A most amusing account of this will be found in the *Life of the Rev. H. H. Parham*, vol. i, p. 176. So greatly were some of the foreign potentates impressed with the importance of Frost and his Society that two of them sent the insignia of one of their minor orders to the Director. These Frost appropriated and duly wore at all meetings of the Society. Some of the papers read were of considerable interest and importance, but, especially in the later years no proper supervision was exercised in the matter laid before the Society; in fact, Earl Stanhope would admit anything which could be dressed under the head of medical botany. To such an extent was this carried, that Mr. Clarke relates the case of a keeper of a herb bath who "read a paper to show that influenza, at that time epidemic, was caused by the cows eating buttercups, which in that season were most prolific." Frost's conduct became at last so overbearing that his colleagues could not submit to it. The result of the quarrel was that the office of Director was abolished, and Frost himself was expelled from the Society. The other Secretary was Dr. Sigmond, a man of very considerable learning. Whenever there was a lack of material for discussion, it was customary to fall back on Dr. Sigmond for a paper; among his communications may be mentioned one which in 1834 he brought before the Society on the subject of Endermic Medication. Three parts of *Transactions* were issued, the first containing the work of the Society for 1821-29, the second 1832-38, and the third 1834-37. Earl Stanhope was the mainstay of the Society in its later years, and soon after his death in 1855 it ceased to exist.

THE HARVEIAN SOCIETY OF LONDON

was founded in the year 1831. The want of a society of this kind had long been felt by those who were practising in the western part of London. The preliminary meeting was held at the Western General Dispensary in Lisbon Grove on September 12th, 1831, Dr. A. T. Thompson in the chair. It was then unanimously resolved that such a society should be established under the name of the Western London Medical Society. On September 15th the Society was formally constituted and the first officers were elected. At a meeting held on September 25th it was decided to change the name of the Society from that originally suggested to the Harveian Society. The early meetings were held at the Western General Dispensary, but before the end of 1834 apartments for this purpose were engaged at 23, Edward Street, Portman Square, from whence in 1835 the Society moved to the Marylebone Literary and Scientific Institution in the same street. A "Harveian Lectureship" has been instituted by the Society for the delivery of two or three lectures on some subject of practical interest in medicine, surgery, or midwifery. The Society does not publish any transactions, but its meetings are reported in the medical journals.

THE SOUTH LONDON MEDICAL SOCIETY

was founded in 1832; the preliminary meeting, under the chairmanship of Mr. Edward Evans, was held at the apartments of the Southwark Literary Society, Chester Terrace, Southwark. The Society was originally to have consisted of general medical practitioners of Southwark and its vicinity. The last reported meeting was held on August 16th, 1849, under the presidency of Mr. Hilton, to discuss the Treatment of Cholera. A thesis's first paper on Disease of the Supra-renal Capsules was read before the South London Society on March 14th, 1849. A report of it may be found in the *London Medical Gazette*, n.s., viii, 1849, p. 517. Another society with this title was formed in 1867 (*vide infra*).

THE SOCIETY OF MEDICAL AND SURGICAL OBSERVATION

was founded in 1839 to collect and arrange authentic histories of disease and to disseminate among the members a knowledge of the cases under treatment in the different London hospitals. The meetings were held at the members' houses, the president for the evening being the member at whose house the meeting was held. Mr. (afterwards Sir W.) Bowman was the first Secretary. The last meeting was held on April 30th, 1860, at the house of Mr. Partridge. It was then decided to dissolve the Society, and it was ordered that all the papers should be arranged and deposited, with the minute book, in the Royal Medical and Chirurgical Society's Library.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION

is the successor of a society started in 1841 under the title of the Association of Medical Officers of Hospitals for the Insane. This Association originated in a circular addressed in 1841 to eighty-three medical men connected with the public lunatic asylums in the kingdom. The circular was signed by Dr. Samuel Hitch, the resident physician of the Gloucester County Asylum, and asked whether, in starting the Association, co-operation might be expected. Forty-four favourable replies were received, and a meeting of those who agreed to join the Association was held at the Gloucester Asylum on July 27th, 1841. At this meeting the Association was formally started, and it was decided to meet annually at a private or public lunatic asylum. For some time the Association contemplated publishing a journal, but it was not until 1862 that it was definitely decided to issue one. The title chosen was the *Asylum Journal of Mental Science*, and Dr. Bucknill was appointed the first editor. In 1859 the title was changed to the *Journal of Mental Science*, under which name it still appears.

THE SYDENHAM SOCIETY

was formed in 1843 for the purpose of meeting certain deficiencies in the diffusion of medical literature not likely to be supplied by the efforts of individuals. The Society issued between the years 1844 and 1857 many valuable works, including editions of *Paulus Aegineta*, *Rhazes*, *Hippocrates*, and *Avicenna*. In 1857 the Society was dissolved, the Council giving as its reason for this act that the work for which the Society was established was completed.

THE NEW SYDENHAM SOCIETY

was established in the year 1838 for the purpose of carrying on the work abandoned by the original Society. Dr. C. J. B. Williams was elected the first President; the success of the Society, however, has been mainly due to Mr. Jonathan Hutchinson, who has held the post of honorary secretary from the foundation of the Society until the present time. In addition to publishing many useful books, the Society has issued an Atlas of Pathology and another of Diseases of the Skin, and has partly completed a *Dictionary of Medical Terms*.

THE WESTERN MEDICAL AND SURGICAL SOCIETY

was founded in 1845, and held its meetings in Sloane Street, Mr. Benjamin Brodie was one of its presidents, and his presidential address is printed in Mr. Charles Hawkins's edition of Brodie's works. The Society had a fair library of modern books; these chiefly came from the Chelsea and Brompton Medical Society, which presented the books which had been in circulation during the year previous to their deposit in the library of the Western Medical and Surgical Society. Owing to a great decrease in the number of members, which was chiefly caused by the establishment of other London societies, the Western came to an end in 1871. The books belonging to the Society were given to the Medical Library at St. George's Hospital, to which a large number of the members belonged.

THE PATHOLOGICAL SOCIETY OF LONDON.

In February, 1846, Dr. Edward Bentley, of Guy's Hospital, made an endeavour to start a separate society for the discussion of pathological subjects. This need was felt from the reluctance there was in the existing societies to devote any of their meetings solely to pathology. Dr. Bentley and Mr. Nathaniel Ward were appointed secretaries of a provisional committee formed to make the preliminary arrangements for starting the Society. A prospectus was issued by this Committee to the members of the profession setting forth the objects of the new Society. This appeal met with unexpected support, and on October 20th, 1846, at the first meeting 106 members were enrolled. Dr. C. J. B. Williams was appointed the first President, and it was at his suggestion that a medallion of the head of Dr. Matthew Baillie was chosen as the seal of the Society with the motto "*Nascitur mori*." This has been stamped on the covers of all the volumes of *Transactions* up to the present day. The first volume of *Transactions* was published in 1848, and the yearly volumes have been continued without a break.

THE EPIDEMIOLOGICAL SOCIETY OF LONDON

was instituted on July 30th, 1850, at a meeting held at the Grosvenor Square Rooms under the presidency of Lord Ashley, afterwards the Earl of Shaftesbury. The object of the Society was the investigation of past as well as of existing epidemics not only amongst the human race, but also amongst animals. In addition to the discussion of papers calculated to carry out this object, the Society has endeavoured to further extend its work by the appointment of committees to investigate the causes, etc., of the various epidemic diseases. From 1855-58 the *Transactions* of the Society were issued with the *Journal of Public Health and Sanitary Reform*. Since the latter date the *Transactions* have been regularly published in a separate form.

THE LONDON MEDICAL SOCIETY OF OBSERVATION

was founded in 1850 by Drs. Walter Jenner, Parkes, Snow, Mack, Barn, and Snowling. Dr. Walter was the leading spirit in starting the Society, and was elected its first President. The number of members was limited, and the meetings were held at the houses of the various members in rotation. By the founders of the Society its objects were thus stated: "To promote the advancement of accurate pathology and therapeutics by clinical and allied investigations, the value of which shall be estimated by the numerical method; and to exhibit the special advantages which may accrue to the science of medicine by the co-operation of several persons working on a uniform plan towards the elucidation of given medical questions." These objects were to be pursued "by the collection of records of cases observed by the members, the particulars in every instance (whether observed at the

bedside or after death) to be noted in writing at the moment of observation, fulness of detail to be constantly held in view as deeply important, but accuracy alone to be considered absolutely necessary. By the accumulation of observations of special phenomena of disease and the relations subsisting between them, with the view of ascertaining their regulating laws; it being understood that the subject and the plan of observation shall, in each instance, be sanctioned by the Society." To accomplish these ends a handbook was issued by the Society in 1853 under the title *What to Observe at the Bedside and after Death in Medical Cases*. This book was published under the direction of a Committee, but the general supervision was entrusted to Dr. Ballard. It was originally proposed to publish an analysis of the cases accumulated, but this was never done. Part of the material got together was used by some members of the Society, but the original papers were returned to the Secretary. All the manuscripts of the Society were left in the hands of the late Dr. Wilson Fox, who was the last secretary.

THE NORTH LONDON MEDICAL SOCIETY

was founded in 1853 mainly through the exertions of Professor Sharpey, Mr. Richard Quain being the first President. The meetings were held at Bedford Schoolroom, Charrington Street, Oakley Square, and subsequently at 30, Albert Street, Camden Road. The Society had not a very prosperous career, and ceased to exist about 1885.

THE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH

was formed by the medical officers of health in the metropolis in 1856 for the purpose of mutual assistance and the advancement of sanitary science. At the time of the formation of the Society there were forty-seven medical officers of health in the metropolis, nearly all of whom became original members. Mr. (now Sir John) Simon was elected the first President, and committees were appointed to inquire into subjects relating to the public health. In 1873 the name was changed from "Association" to the "Society of Medical Officers of Health." The annual reports of the Society were published in separate form from 1868 to 1879; from 1879 to 1886 *Transactions* were issued; since 1886 no separate publication has been issued by the Society. The proceedings are reported in *Public Health*.

THE ODONTOLOGICAL SOCIETY OF LONDON

was formed in 1856 mainly for the purpose of carrying on the movement then on foot for obtaining from the College of Surgeons some recognised qualification for those who were practising this branch of surgery. A memorial on this subject was forwarded to the College in 1855, and in November, 1856, a meeting of those interested in the new Society was held at which the by-laws were agreed to, and Mr. Cartwright was appointed the first president. In 1861 the title was changed to the "Odontological Society of Great Britain." The Society has a library and museum, and has published *Transactions* regularly since 1856.

THE ARMY MEDICAL AND SURGICAL SOCIETY

was started in 1856, shortly after the termination of the Crimean war, Dr. (afterwards Sir J.) Gibson being the President, and Mr. (afterwards Sir J.) Mount the Secretary. The members consisted of medical officers in London, Woolwich, and Aldershot, and its meetings were held in Sackville Street, Piccadilly. The Society existed only a few months, coming to a sudden termination on the outbreak of the Indian Mutiny, which scattered its members, most of whom were ordered on service. The meetings were chiefly taken up by discussions of interesting cases which occurred during the campaign.

THE OBSTETRICAL SOCIETY OF LONDON.

The meeting for inaugurating this Society was held at the Freemasons' Tavern on December 6th, 1858, Dr. Rigby in the chair. The object of the meeting was stated to be the formation of a Society for the purpose of the advancement of the knowledge of obstetrics and the diseases of women and children. On the motion of Dr. Tyler Smith, seconded by Dr. Grayson, it was agreed to start a Society on the lines laid down. In 1859 an attempt had been made by Dr. Greenough

to start a similar Society. A meeting was held at his house, under the chairmanship of Sir Charles M. Clarke, for the discussion of the subject. To the majority of those present the scheme, as proposed by Dr. Granville, seemed too large, and only that part of it was adopted which dealt with the political or State part of the question. Dr. Granville claimed that this was not without result, as by the action of that Society obstetricians had been enabled to take a more honourable place amongst the medical practitioners of the three corporate bodies. The first meeting of the Obstetrical Society was held on January 5th, 1859, Dr. Rigby, the first President, being in the chair. The meetings have always been held in the house of the Royal Medical and Chirurgical Society, but in 1868 apartments were opened at 291, Regent Street, for the Society's library and museum; in 1882 the Society took rooms at 54, Berners Street. When the Royal Medical and Chirurgical Society moved to Hanover Square the Obstetrical went with them. The Society has a good library, the books from which are lent out to the Fellows for use at home; there is also a museum of casts, models, and instruments relating to the obstetric art.

THE BRAUMONT MEDICAL SOCIETY

was started in 1865, and held its meetings at the Beaumont Institution, Mile End. The Society came to an end in 1876 or 1877.

THE CLINICAL SOCIETY OF LONDON.

The Clinical Society owes its origin mainly to the energy of Drs. Headlam Greenhow and Burdon Sanderson. Under the presidency of the former physician, a private meeting was held at 49, Queen Anne Street on October 29th, 1867, to take into consideration the desirability of forming a Society "for the cultivation and promotion of practical medicine and surgery by the collection of cases of interest, especially of such as bear upon undetermined questions in pathology and therapeutics." At this meeting a Provisional Committee was appointed to carry out this object, and a Subcommittee, consisting of Dr. Buchanan, Mr. Callender, Dr. Greenhow, Mr. Heath, Dr. Ringer, and Dr. Burdon Sanderson was nominated to prepare a draft set of rules for the Society. Invitations to join the Society were then sent round to the members of the staffs of all the recognised metropolitan hospitals and medical schools, and it was determined to hold a meeting on December 9th, 1867, of all who should have signified their intention of joining the new Society. At this meeting it was reported that 110 original members had joined the Society. Dr. Greenhow was voted to the chair, and the election of the first officers took place, with the result that Sir Thomas Watson was appointed the first President, and Dr. Burdon Sanderson and Mr. Callender the first Secretaries. The Society has regularly issued volumes of *Transactions* since 1868. In 1883 a Committee, under the chairmanship of Dr. Ord, was appointed to consider the subject of Myxœdema; this Committee reported to the Society in 1888, and their valuable report was issued as a Supplement to the twenty-first volume of the *Transactions*. In 1892, as a Supplement to the twenty-fifth volume, the Society issued, under the editorship of Dr. Dawson Williams, the report of a Committee appointed to investigate the Periods of Incubation and Contagiousness of Certain Infectious Diseases.

THE SOUTH LONDON MEDICAL SOCIETY.

The second Society under this title was formed in 1867. In November of that year a preliminary meeting was held at the Ophthalmic Hospital, Southwark, Mr. J. Z. Laurence in the chair. A committee was appointed to carry out the details of forming the Society, and on December 3rd the first meeting was held, Dr. Clapton being appointed President, and Messrs. R. C. Moon and J. H. C. Constable, Secretaries. The Society had a prosperous career for about five years; at the end of that period financial difficulties and the deaths of the Honorary Secretaries caused the meetings to be discontinued.

THE MEDICAL MICROSCOPICAL SOCIETY

was founded in 1872 mainly through the exertions of Mr. J. W. Groves. The preliminary meetings were held at St. Bartholomew's Hospital under the chairmanship of Mr. Morrant Baker. The Society started with thirty-nine original members and Mr. Jabex Hogg occupied the presidential chair for the first two sessions. The objects of the Society

were stated to be the "discussion of questions of normal and pathological histology, medico-legal and medico-chemical microscopy, and mechanical and optical arrangements requisite for the proper examination and preparation of microscopic specimens." The meetings were held in the Board room of the Royal Westminster Ophthalmic Hospital. The Society lasted for about eight years; the cause of its breaking up was chiefly that the subscription, half a guinea, was too small to meet the expenses and assist the members in research.

THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

This Society was formed in 1880. In response to an invitation issued to those interested in ophthalmology, a meeting was held at the rooms of the Medical Society of London on June 23rd, 1880, under the chairmanship of Mr. (afterwards Sir William) Bowman. The Chairman having delivered an address, the business of forming the Society was proceeded with, and on the motion of Mr. Critchett, seconded by Dr. Hughlings Jackson, it was unanimously agreed "That an Ophthalmological Society of the United Kingdom be formed." Mr. Bowman was elected the first President, and Dr. Stephen Mackenzie and Mr. Nettleship were the first Secretaries. Before this meeting, fifty gentlemen had agreed to join the Society when formed, and at the meeting thirteen others were enrolled as original members. The Society has issued *Transactions* regularly from 1880. It has a library of books bearing on the subject to which the Society is devoted.

THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY

was founded in 1882 at a meeting held in the Board Room of the West London Hospital, under the presidency of Dr. Goddard Rogers. The first meeting of the Society was held on October 6th, 1882, Dr. E. Hart Vinen, the President, in the chair. An annual lecture is given before the Society by some eminent man of science. This is called the Cavendish Lecture, after Henry Cavendish, who lived for some time near the spot where the Society meets. The first of these lectures was given by Mr. Timothy Holmes in 1884. The Society has issued five volumes of *Proceedings*.

THE DERMATOLOGICAL SOCIETY OF LONDON

was founded in 1882 for the exhibition of cases only. The number of members was limited to thirty, but in May, 1895, it was decided to withdraw the limit.

THE BRITISH GYNÆCOLOGICAL SOCIETY.

The preliminary meeting for discussing the desirability of forming a Society to promote and encourage the science of gynecology was held at the rooms of the Medical Society on December 27th, 1884, under the chairmanship of Dr. Routh. A resolution as to the desirability of founding such a Society was moved by Dr. Robert Barnes, seconded by Dr. Haywood Smith, and carried unanimously. The election of officers was then proceeded with, Dr. Alfred Meadows being elected the first President. The new Society received considerable support from all parts of the country, so that the secretaries were able to report that the number of foundation Fellows amounted to 266. The first meeting was held on March 11th, 1885, in Chandos Street; here the Society continued to meet until the Royal Medical and Chirurgical moved to Hanover Square, when rooms were secured there by the British Gynecological Society. The Society has a small library, the nucleus of which was the collection of books belonging to Dr. Alfred Meadows, which came into the possession of the Society at that gentleman's death. The *British Gynecological Journal* has been published regularly by the Society since 1885.

THE NEUROLOGICAL SOCIETY OF LONDON.

This Society originated at a meeting held on November 14th, 1885, when, on the proposition of Dr. Broadbent, seconded by Dr. Hughlings Jackson, the desirability of forming such a Society was agreed upon. A Committee was appointed to draw up rules and to nominate a Council and officers. The report of this Committee was agreed to at a meeting held on January 14th, 1886. The first ordinary meeting was held at the National Hospital, Queen Square, on March 24th, when Dr. Hughlings Jackson, the first President, delivered an

THE PRINCE OF WALES, in reply, said that it gave much pleasure to him and to the Princess to be present to take part in so interesting a ceremony. The College was in a flourishing condition, and he trusted that it would long continue to flourish. He had always taken an interest in Kusun College, and was glad to lay the foundation stone of the

Lower School, which would increase the College, and would increase also, he hoped, its usefulness.

The ARCHDRAGON OF MIDDLESEX (the Ven. R. Thornton, first head master of Epsom College) having offered prayer, Mr. LUMSDEN PROBERT, a son of the founder, handed to the Prince a series of coins of the day and a copy of the *Times* and an illuminated scroll, which the Prince deposited in a hollow in the foundation stone, and then laid the stone, with the assistance of Sir Arthur Blomfield, the architect.

The "Old Hundredth" was then sung by the boys, after which the ARCHDRAGON OF SURREY (the Ven. J. H. Sapse) gave the benediction, and the formal part of the ceremony ended, but the Prince and Princess of Wales and the Princess Victoria subsequently walked across the lawn, and were conducted by members of the Council to the library and other parts of the College buildings before returning to London.

The guard of honour at the entrance on arrival was furnished by the College Cadet Corps.

The new Lower School will contain six dormitories for 100 boys, five class rooms, a dining hall, box rooms for boys changing for play, sick rooms, kitchen and offices, full servants' accommodation, wardrobe, matron's and serving rooms, as well as a masters' house with accommodation for five unmarried masters. The total cost of these buildings—which are to be constructed of red brick with Bath stone quoins and dressings—is estimated to be £12,320. An addition is also to be made to the chapel, which will cost about £2,500. For these purposes further donations are required, and will be acknowledged by Mr. J. Bernard Lamb, Secretary of the College, 37, Soho Square, W.

THE MEETING OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ATTRA the declaration of the poll on July 4th at the Royal College of Surgeons the half-yearly meeting of the Fellows took place in the Theatre of the College. Mr. CHRISTOPHER HEATH, President, who occupied the chair, referred to the loss which the College had sustained during the past year in the death of the late President, Mr. John Whitaker Hulke, Sir William Savory, Mr. Durham, and Professor Huxley. Mr. Heath then reported that the following alterations in the by-laws had been approved by the Home Secretary, namely: (1) An alteration in Subsections 5 and 6 of Section IV, providing that voting papers for the election of members of the Council shall be sent to the Fellows without the necessity of application, and that they shall be received up to the time appointed for the commencement of the election. (2) An alteration of Section XVI, giving the Council increased powers to deal with cases of misconduct by Fellows and Members of the College. (3) An alteration of Subsection 8 of Section XXV, providing for the increase of the fee for the Licence in Dental Surgery from ten to twenty guineas. Mr. Heath further stated, with reference to the alteration of Section XVI, that certain Members of the College had written to the Secretary of State objecting to the alteration of that Section in the form originally adopted by the Council and approved by the meeting of Fellows on July 5th, 1894, and by the meeting of Fellows and Members on November 1st, 1894, and urging that, in view of the harsh nature of Section XVII, no alteration in the by-laws should be sanctioned which did not include either its amendment or entire abrogation: that the Secretary of State had given the Council the opportunity of replying to the objections raised, and having considered the representations made to him by both sides had suggested that a single paragraph in terms similar to those of the Medical Act of 1858 should be substituted for the proposed paragraphs 1, 2, and 3; that after consultation with their legal advisers the Council had adopted the suggestion of the Secretary of State, and had ordained the by-law in the following form:

SECTION XVI. Misconduct of Fellows and Members.

1. If any Fellow or Member of the College shall, after due inquiry, be judged by the Council to have been guilty of disgraceful conduct in any professional respect, he shall be liable to removal by resolution of the Council from being a Fellow and Member of the College.

2. Should any Fellow or Member of the College be convicted of any criminal offence, or have his name removed from the Medical Register by the General Medical Council under section XXIX of the Medical Act of 1886, the Council of the College may, if they should consider the offence

of which he shall have been so convicted, or for which his name shall have been so removed, to be of such a nature as to render him unfit to remain a Fellow and Member or a Member of the College, remove such Fellow or Member by resolution to that effect from being a Fellow and Member or a Member of the College.

3. Any Fellow or Member who shall have been removed by resolution of the Council as aforesaid shall thereby forfeit all his rights and privileges as a Fellow and Member or a Member of the College; and his diplomas or diploma shall thereupon be void and shall become the property of the College, and be delivered up by such Fellow or Member to the College on demand, provided that if at any subsequent time the Council of the College, by resolution and subject to such conditions as they may think proper, rescind any resolution which may have been passed under any of the preceding by-laws for removing any person from being a Fellow and Member or Member of the College, such rescinding of the former resolution shall have the effect of restoring such person to the Fellowship or Membership of the College, and such person shall, notwithstanding such removal or forfeiture as aforesaid, but subject to such conditions as the Council may in the particular case see fit to impose, be restored to his rights and privileges as a Fellow and Member or a Member of the College.

It was also announced that in reference to the resolution adopted at the last meeting of Fellows requesting the Council to appoint a conjoint committee of members of the Council and other Fellows of the College to consider the desirability of obtaining a new charter, the Council had passed the following resolutions:

1. That in accordance with the opinion of the legal advisers of the College the Council do not deem it expedient to accede to the resolution passed at the meeting of Fellows held on January 3rd.

2. That a Committee of the Council be appointed to receive deputations from the Fellows of the College upon the subject of the resolution of the meeting of Fellows on January 3rd last, and to report thereon to the Council.

3. That copies of the foregoing resolutions be forwarded to the mover and seconder of the resolution of the meeting of Fellows.

Mr. HEATH said that on June 10th last the Committee of the Council received a deputation from the Association of Fellows by whom certain suggestions and recommendations were made in respect to the by-laws and charters. After a long discussion the deputation were asked to express their views in writing, and this request had been complied with. The Committee of the Council would hold a meeting on the following day in order to take these recommendations into consideration and then draw up their report with a view to laying it before the Council at an early meeting.

There was no other business upon the agenda, and accordingly Mr. Heath declared the meeting closed.

LITERARY NOTES.

THE *Handbuch der speciellen Therapie innerer Krankheiten*, edited by Professors Penzoldt, of Erlangen, and Sautzting, of Jena, and published by Fischer, of Jena, has now reached the twentieth fasciculus. The excellence of the articles contributed by the distinguished authorities whose co-operation the editors have been fortunate enough to secure is fully maintained.

The following letter shows that in the reign of Bluff King Hal doctors sometimes found it difficult to recover their fees. It is preserved in the Record Office among the uncalendared papers (30 Hen., viii U. 198):

My singular good Lorde.—After my most bounden duetye to your Lordshyp, this shalbe to advertize the same, that wheras of late the Byschoppe of Rochestre at what tyme he was sycke, requyred me to loke to hyme and to gyve attendaunce on hyme bothe nyght and daye, promysynge to recompense my labour and payne, and wher after he was departede, all hys goodys war taken upp by Mr. Gostwycke and converted to the Kyngs Coferys, so that for xlii dayes labour, and xlii nyghts watchynge, as yet I have recoveryd nothinge, in so muche, that except your lordshype be good to me, I shall bothe lose my labour, my payne and also my physycke, and trulye if physycyens shuld take no paye for them, that they kyl, as well as for them that they save theyr byng made to very thynge and bare, therfor I beseeche your good Lordshype as to send to Mr. Gostwycke that I may have some recompense and reward for my payne. And I beseeche your Lordshype it may be so muche the more libéral, because it shalbe the last payement, for of them that scape we may take the least, because we hope they shall yet come agayne into our handys. I beseeche your good lordshype, as I have in many other thynges ever founde yor Lordshype good to me, so also in this my pover request, lett me not be destitute of your wofull favour and goodnes towards me, as I shal daily pray for the preservation of your healtie, the whiche I pray God longe to maintayne and kepe in all honor and loundre.

From London the xviii of August

Yor Lordshype hys most humble servaunt

JONAS VVYN physyctyen.

To my ryght honorable and my singular good Lord, my Lorde Privy Seale.

One cannot help hoping that the worthy "physyctyen" succeeded in making the "Kings Coferys" disgorge enough to satisfy his just demand.

ASSOCIATION INTELLIGENCE.

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

Members are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the offices of the Association, 419, Strand. The rooms are open from 10 A.M. to 5 P.M. Members can have their letters addressed to them at the Office.

NOTICE OF LAST QUARTERLY MEETING FOR 1895.
ELECTION OF MEMBERS.

A MEETING of the Council will be held on October 23rd, 1895. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before the meeting—namely, October 2nd, 1895.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWKE, General Secretary.

BRANCH MEETINGS TO BE HELD.

SOUTH OF ENGLAND BRANCH.—The annual meeting of this Branch will be held on Thursday, July 26th, at 5 P.M., at the Royal Hotel, South Shields. Dr. Crisp, President-elect, will deliver the annual address; and the officers of the Branch will be elected. The dinner after the meeting will take place at the Royal Hotel, at 6 P.M., 6s. 6d. each, wine not included. —G. E. WILLIAMSON, F.R.C.S., Honorary Secretary, 8, Eldon Square, Newcastle-on-Tyne.

NORTH OF IRELAND BRANCH.—The annual meeting of this Branch will be held in the Royal Hospital, Belfast, on Thursday, July 18th, at 11.30 A.M. Lunch will be provided in the Grand Central Hotel, at 2 P.M. Tickets, price 2s. 6d., may be obtained from the Honorary Secretary, JOHN CAMPBELL, M.D., F.R.C.S. Eng., Belfast.

DORSET AND WEST HANTS BRANCH.—The next meeting will be held at Dorchester on July 17th. The business meeting will be held at the Town Hall at 8 P.M. Agenda:—Election of new members of the Branch. Place of the autumn meeting. Receive report from the Committee on the Office of Medical Charities. Dr. MacDonald to move the following alteration in By-Law VII:—“The Council of the Branch shall consist of the President, the two Vice-Presidents, the two Honorary Treasurers and Secretaries, and nine elected members, three of whom shall retire in rotation at the annual meeting, and shall not be eligible for re-election for twelve months.” In the event of this resolution being carried, Dr. Lewis to move: “That nine members of Council be elected in May, 1896, and that in so retiring in 1897 and 1898 shall do so in alphabetical order.” A resolution from three members of the Association relating to proposed extension of the Association's work. Discussion: (To be opened by Mr. T. W. Blake, Vice-President), Is Cancer a Waterborne Disease? with special reference to its Occurrence in Chalk Valleys and Districts of the Hampshire and Dorset Springs and Rivulets. Communications:—Dr. Lewis to report on specimens removed from Two Cases of Abdominal Section. Dr. Carter to report on a new Ether Inhaler. Mr. Ewens: Enucleation of the Parotid Glands. Dr. Clibborn and Mr. Hay will be pleased to see members and friends at their residences to luncheon before the meeting. Dinner at the Bell Hotel, at 5 P.M., charge 6s. each, without wine. Members intending to be present are requested to notify their intention to the Hon. Secy. by Monday, July 16th.—WILLIAM YANDREY LUSH, M.D., Weymouth, and C. H. WATTS PARKINSON, Wimborne, Honorary Secretaries.

EDINBURGH, GLASGOW AND WEST OF SCOTLAND,
PERTHSHIRE, AND STIRLING, KINROSS, AND
CLACKMANNAN BRANCHES.

A combined meeting of these Branches was held in Stirling on July 2nd.

Luncheon and Luncheon.—Sixty members assembled at Stirling Station at 1.45 A.M., where brakes were in readiness, and by the kind invitation of Sir James Maitland, Bart., of Edinburgh, members visited the Howtown Fishery, and in the unavoidable absence of Sir James Maitland were conducted by the foreman, Mr. Thomson, over the hatching houses and culture ponds of this extensive fishery. Much interest was taken in the processes explained by Mr. Thomson, and members were unanimous in expressing their enjoyment of this

most interesting excursion. From the Fishery the members drove to Sauchieburn House to enjoy the hospitality of Sir James Maitland, who most generously invited the whole party to luncheon; in his absence Miss Maitland received the members, and afterwards presided at luncheon. Dr. J. O. McVAIL, President of the Stirling Branch, proposed a most hearty vote of thanks to Sir James Maitland both for the opportunity of visiting the Fishery and for his kindness in entertaining the Branches. Dr. McVail also proposed “The Health of Miss Maitland,” and expressed the appreciation of all the members for her gracious reception. The toast was cordially honoured, and Miss MAITLAND replied in an excellent speech.

The Meeting.—Members drove back to the Smith Institute, Stirling (the use of which had been kindly granted by the trustees) to meet those already assembled for the meeting at 3 P.M. Dr. McVail presided, supported by Dr. Renton, President of the Glasgow Branch and Dr. Philip, Secretary of the Edinburgh Branch.

Communications.—Owing to Professor GAIRDNER being prevented from attending at the last moment Dr. C. O. HAWTHORNE showed on his behalf: 1. A case of Pernicious Anemia in a man showing marked improvement under treatment with raw bone marrow. 2. A man with a loud V. S. Murmur in the Second Left Intercostal Space simulating pulmonic obstruction, but without other evidence of disease of the right heart and with considerable hypertrophy of the left ventricle. 3. Two patients—members of the same family—illustrating the effects of Inherited Syphilis, the elder one with Hutchinson's teeth and slight opacity of one cornea, the younger with Hutchinson's teeth, interstitial keratitis, periosteal thickening over clavicle and ulna, and with enlargement of the spleen. 4. A tracing of Cheyne-Stokes Respiration from a case of Cerebral Softening. 5. Photographs of patients illustrating (a) Hutchinson's teeth, (b) progressive muscular atrophy in a youth aged 17, (c) deformity of hands with muscular atrophy in chronic rheumatoid arthritis, (d) solid oedema in lower limbs of a young woman resulting from repeated attacks of erysipelas.—Dr. J. CRAWFORD RENTON (Glasgow) showed two cases of Abdominal Section: (1) A case of gastro-enterostomy for dilated stomach done three years ago with excellent result. (2) A case of exploratory incision for tumour done twenty months ago, followed by disappearance of tumour. The patient was examined by members present, and no trace of tumour could be discovered.—Dr. LEWIS (Stirling) showed a case of Microcephaly. The child was born eighteen months ago with a swelling in the occipital region, chiefly on the left side of the mesial line. Early closure of the fontanelles followed, and the child was now deficient in intelligence, and quite blind in both eyes; but in other respects it was well developed, and its hearing, smell, and taste were normal. Ophthalmoscopic examination disclosed no abnormality of the fundus.—Dr. MACLEOD (Kilmarnock) showed a case of Fracture of both Femora treated without Splints in which an excellent result had been obtained.—Dr. FINLAYSON (Glasgow) showed Microphotographs from a case studied by a former assistant of his, Dr. H. E. Jones. The man had been in Egypt during the Soudan war, and he applied as an out-patient at the Glasgow Western Infirmary. The case was recognised as being due to bilharzia hematobia. By using some pure water the eggs were hatched by Dr. Jones, and the photographs showed the embryo in the act of leaving the shell, the empty shells and free embryos as well as the ova. No embryos were ever found in the urine itself, although some authorities have described them as seen swimming about in the urine.—Dr. FINLAYSON said that medical Egyptologists recognised this endemic hematuria of Egypt as having been described in the Ebers Papyrus (16); its date was about 1550 B.C. He showed a translation of the passage as rendered into hieroglyphics and phonetics, kindly sent him by Baron Dr. Oefele, of Nuremberg, who was preparing for publication a fresh translation of the Ebers Papyrus.

Surgical Treatment of Erysipelas.—Mr. HENRY E. CLARK (Glasgow) read a paper on the surgical treatment of erysipelas. Effective drainage could be best obtained by making an inch and a-half of the ninth rib below the angle of the scapula. The operation was not a severe one, occupying not more than

three to five minutes. It gave dependent drainage both when the patient was sitting and lying, and it secured an opening as near to the floor of the thorax as was possible without the risk of blockage by the rise of the diaphragm. Having treated more than 40 cases in this way, he had every reason to be satisfied with the results obtained. He reprobated the extensive rib resections which had been recommended and practised by Continental surgeons, and showed a patient who had been operated on nearly three years ago by his method in order to demonstrate the amount of recovery which had taken place in the lung. Although at the time of the operation the dulness extended to the level of the third rib and more than 60 ounces of pus were evacuated, the only part of the lung demonstrable as collapsed after this interval was a small part of the lower lobe. He contended that if more extensive resection had been practised this expansion of the lung could not have taken place; such expansion was, however, more likely to take place in children than in adults, and there were undoubtedly cases where in the latter no expansion was possible, and more extensive resection was imperatively necessary. In one such case at present under his care he had performed Estlander's operation, resecting more than 2 inches of seven ribs (from the fourth to the eleventh), and had obtained a successful result.

Treatment of Syphilis.—Brigade-Surgeon ALEXANDER (Portobello) had made a prolonged study of the treatment at Aix-la-Chapelle, which was yearly crowded by people of every nationality. He attributed the success there obtained to the fearless use of mercurial ointment, the daily use of the hot bath, the thoroughness with which the inoculation was carried out, good dietary, and the absence of spirituous liquors. He did not attach much advantage to the drinking of the special waters of Aix-la-Chapelle, and considered that other things being equal the treatment could be carried out with good results anywhere. For five years he had carried out this treatment as a routine method in the hospital under his supervision with the best results summer and winter, and there appeared to be no reason why many favourably situated resorts should not be utilised for carrying out the treatment thoroughly and successfully for at least nine months out of the year.

Local Results of Vaccination and Variolation.—Dr. J. C. McVAIL (Stirling) showed a number of plates contrasting the local results of vaccination and variolation. The plates were from Jenner's *Inquiry*, and from early works published by Alkin and Pearson in this country, and by the Medical Society of Paris, all about the beginning of the century. In addition, Dr. McVail showed a very beautiful series of unpublished drawings dated 1802, the property of Dr. G. W. Collins, of Wanstead, by whose permission they were exhibited. The drawings illustrate day by day from the second day to the sixteenth the differences between the appearance of the vaccine and variolous vesicles. Dr. McVail's purpose was to indicate that the medical profession in the early days of vaccination was well acquainted with, and had ample means of being acquainted with, the distinctions between inoculated cow-pox and inoculated small-pox; and that, as a matter of fact, the plates of vaccination published between 1775 and 1802 showed vesicles indistinguishable from those of vaccination as known in the present day.

Exhibition of Instruments.—The Medical Supply Association displayed a collection of instruments in the institute during the meeting.

Plants, etc.—At the close of the meeting a section of the members, under the guidance of Dr. Haldane, drove to the Bridge of Allan Mineral Wells where they were met by Dr. Paterson, and were entertained at tea by the Mineral Wells Company. A visit was then paid to Dr. Paterson's house, where the visitors were much interested in his unique collection of curios, and the party returned to the Station Hotel, Stirling. The remainder of the meeting had an opportunity of examining the picture gallery and museum of the Institute whilst afternoon tea was being served. Then they drove to Stirling Castle and other antiquities of the town, the beauties of which were pointed out, and the history related by Ex-Provost Yellowless, of Stirling, who kindly acted as guide to this party.

Dinner.—All the members met again in the Station Hotel at 6 p.m. for dinner. Dr. J. C. McVail presided, and Drs

Strachan and Haldane were croupiers. There were present Dr. Argyll Robertson, Vice-President of the Edinburgh Branch, and Dr. J. Crawford Renton, President of the Glasgow Branch, Dr. Urquhart, Honorary Secretary of the Perth Branch, Dr. Philip, Honorary Secretary of the Edinburgh Branch, Drs. Parry and Nicoll, Honorary Secretaries of the Glasgow Branch, Ex-Provost Yellowless and Provost Kinross, Professor Struthers, Dr. George Buchanan, Dr. Bruce Goff, Dr. T. D. Savill, Dr. Finlayson, etc. After dinner apologies for absence were announced from Sir James Maitland, Bart., Professor Annandale, President of the Edinburgh Branch, Sir Thomas Grainger Stewart, Dr. G. W. Balfour, Professor Chiene, Professor McCall Anderson, Professor Gairdner, Professor McKendrick, Dr. G. A. Gibson, Dr. Byrom Bramwell, Dr. Walker Downie, etc. The following is the toastlist: "Her Gracious Majesty the Queen and the Royal Family," by the Chairman; "The British Medical Association," proposed by Dr. Argyll Robertson, and responded to by Dr. Bruce Goff; "The Associated Branches," proposed by the Chairman, and responded to by Dr. Crawford Renton and Dr. R. W. Philip; "The Guests" proposed by Dr. Haldane, and responded to by Ex-Provost Yellowless; "Sir James Maitland, Bart., the Trustees of the Smith Institute, and the Directors of the Bridge of Allan Mineral Wells Company," proposed by Professor Struthers, and responded to by Provost Kinross, Trustee of the Smith Institute. The "Health of the Honorary Secretary" was proposed by Dr. Spence, and that of "The Chairman" by Dr. George Buchanan.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.

The twenty-fifth annual meeting of this Branch was held at the Swansea Hospital on June 25th.

Installation of New President.—Dr. MULLIGAN, the retiring President, having resigned the chair to Mr. J. GRIFFITH LOCK (Tenby), the President-elect, a unanimous vote of thanks was passed to Dr. Mulligan for his services during the year.

Confirmation of Minutes.—The minutes of previous meeting read and confirmed.

New Member.—Dr. Blagdon Richards, of Swansea, was elected a member of the Branch.

Report of Council.—The report stated that the number of members was 241, as compared with 228 last year and 223 the year before. Hitherto only two meetings had been held in the year in addition to the annual meeting. During the past year a new departure was taken by resolving to have two additional meetings—one at Cardiff, the other at Swansea—to be held as late in the afternoon as possible, devoted entirely to reading of papers and showing of cases, and not to be followed by the usual dinner. The first of these meetings was held at the Cardiff Infirmary on April 30th, at 3.30 p.m., and was an undoubted success, upwards of forty members attending. Some interesting cases were shown and valuable papers read. The usual autumn and spring meetings were held—the one at Pontypool, and the other at Aberdare; both were well attended. During the year numerous interesting papers had been read and cases and specimens shown. The following matters had also been discussed: The proposed amendment of the penal clauses of the Medical Acts. Proposal to alter rules so that retiring members of Council shall not be eligible for re-election. The subject of midwives registration. The desirability of the British Medical Association taking power to proceed against unqualified practitioners. The abuse of medical charities. The Medical Acts Amendment Bill. The statement of accounts showed a balance to the credit of the Branch of £78 6s. 10d. It was announced that the autumn meeting would be held at Bridgend and the spring meeting next year at Tenby. The next business meeting would be held at Swansea in September. The report went on as follows: "On this, our twenty-fifth anniversary, it seems not inappropriate that we should give a short history of our past life. The resuscitation of the South Wales and Monmouthshire Branch was due to the energy of Dr. Andrew Davies (late of Swansea), whom we are pleased to still have with us. Our first annual meeting was held here at the Swansea Hospital in June, 1871, Mr. Padley being our first President and Dr. A. Davies and Dr. Sheen Honorary Secretaries. Prior to this time, however, there was a South Wales and Monmouthshire Branch, for in 1852 a

Branch was formally constituted, with the late Mr. W. H. Michael, then partner of Mr. Ivor Davies, of Swansea (who is present here to-day), and afterwards a distinguished member of the Bar, as Honorary Secretary. The parent Association met at Swansea in 1863. In 1865 the Branch held its meeting at Abergavenny, with Glencis J. Steel as President, and in 1866 in Cardiff, with the late Dr. C. E. Vachell as President. Mr. Michael then left Swansea, and the Branch soon became defunct. Our membership in 1871 was 167, whereas we now number nearly 250. Dr. Andrew Davies and Dr. Sheen worked together as Honorary Secretaries till 1879, when Dr. Davies resigned owing to his having given up the active duties of his profession, and Mr. J. H. Wathen joined Dr. Sheen as joint Honorary Secretaries, but resigned on his removal to Clifton in 1881, when Dr. Arthur Davies was appointed in his place. Since that time we have gone on prospering, and now, as a Branch, occupy one of the highest positions, being sixth or seventh in the list as regards the number of members."

Election of Officers.—The following were elected for the ensuing year: *President-elect*, Dr. Redwood, Rhymney; *Members of Council*, H. A. Latimer, T. J. Webster, J. G. Hall, J. A. Rawlings, and E. P. Evans; *Honorary Secretaries*, A. Sheen and D. A. Davies; *Representatives on Council*, Dr. Sheen and Mr. Evan Jones; *Parliamentary Bills Committee*, Mr. Evan Jones.

Abuse of Medical Charities.—Dr. SHEEN read a report regarding Swansea Hospital. Mr. HORDER read an independent report regarding Cardiff Infirmary, pointing out that, in his opinion, there was much abuse of the out-patient department of this institution, and in this particular disagreeing with Dr. Sheen, who considered there was not much ground for complaint. There was no report regarding Newport Infirmary. There was a good deal of discussion, and ultimately the following resolutions were passed:

1. This meeting receives with thanks the reports of the Subcommittee, but thinks that the information is not full enough to enable it to form an opinion on the matter. It therefore refers the matter back for further consideration and report.

2. That in all inquiries made into the abuse of out-patient departments in hospitals, definite inquiries should be made of patients as to their incomes, families, and charges on those incomes, and that no return can be considered satisfactory which is made without these inquiries.

Mr. C. Griffiths was appointed on the Subcommittee in place of Dr. Sheen, who declined to act further, and Dr. Latimer in place of Mr. Hopkins.

Proposed Alteration of Rules.—Mr. Collins's resolution re alteration of rules was deferred to the November meeting at Bridgend.

The British Medical Association and the Protection of Medical Interests.—On the motion of Mr. HORDER the following resolutions were passed:

That this meeting is of opinion that the Council of the Association should without delay take into consideration the best way of applying a portion of the surplus funds of the Association in proceeding against unqualified practitioners and other persons who are in the habit of practising medicine and surgery without legal qualifications.

That a copy of this resolution be sent to the General Secretary, to be placed on the agenda at the annual meeting in London.

SOUTHERN BRANCH.

The annual meeting of this Branch was held at Salisbury on June 27th, forty-nine members being present. Professor CAYLEY (Royal Victoria Hotel, Netley) was in the chair.

Election of Officers.—The following officers were elected for the ensuing year: *President*: Mr. Harcourt Coates, Salisbury. *President-elect*: Dr. Watson, Southsea. *Vice-Presidents*: Professor J. Lane Nottter, Netley; Dr. Axford, Southsea. *Members of Council*: Messrs. Knott, Wade, Darke, Sinclair Coghill, Brook, Harman. *Representative on Parliamentary Bills Committee*: Mr. Langdon, Winchester. *Representations on Council of Association*: Dr. Trend, Southampton; Mr. H. J. Manning, Laverstock. *Honorary Secretary and Treasurer of the Branch*: Mr. H. J. Manning, Laverstock.

Communications.—Interesting papers and specimens were submitted by Messrs. PULLAR, LANGDON, BROWN, LEE, and LUDHAM.

Installation of New President.—Professor CAYLEY resigned

the chair to Mr. HARCOURT COATES, who delivered the address, for which a vote of thanks was proposed in cordial terms by Mr. CHRISTOPHER HEATH (President Royal College of Surgeons), who was present as a visitor, and carried by acclamation.

Registration of Midwives.—Mr. LANGDON reported to the meeting that a subcommittee of the Parliamentary Bills Committee had drafted a Bill for the registration of midwifery nurses, and desired the opinion of the Southern Branch thereon. It was resolved to refer the Bill to each of the districts for consideration, and Mr. Langdon undertook to forward a copy to each district.

Visit to Langford Castle.—During the afternoon a visit was paid to Langford Castle, the seat of the Earl of Radnor, who kindly threw open the picture galleries.

Dinner.—In the evening the members and their friends dined together at the County Hotel, Salisbury, the Mayor of Salisbury, the Dean, Mr. Hulke, M.P. for Salisbury, Viscount Folkestone, M.P. for the southern division of Wiltshire, and Mr. Christopher Heath being among the guests.

Next Annual Meeting.—It was decided to hold the annual meeting of 1896 at Southsea, under the presidency of Dr. Watson.

OXFORD AND DISTRICT AND GLOUCESTERSHIRE BRANCHES.

A COMBINED meeting of these Branches was held at Oxford on July 5th.

Annual Meeting of Oxford Branch.—Previous to the combined meeting, the annual meeting of the Oxford Branch was held at the same place. In consequence of the illness of the President, Dr. Hutcheson, the chair was taken by Mr. A. WINKFIELD.

Confirmation of Minutes.—The minutes of the last meeting were read and confirmed.

Report of Council.—The report of the Branch Council was read. It stated that the Treasurer had a balance in hand of £41 15s. There were 102 members, and the Council was glad to report the continued prosperity of the Branch. The Treasurer's report was read and adopted.

Contribution to the Expenses of the Annual Meeting.—It was proposed and carried that the Treasurer be allowed to contribute a sum not exceeding £20 towards the expenses of entertaining 200 members of the British Medical Association on August 3rd; and that a Committee consisting of Mr. Symons, Mr. Winkfield, Mr. Morgan, Dr. Collier, and Dr. Dixie be appointed to carry out the arrangements.

Installation of President.—Mr. HORATIO P. SYMONDS was then installed in the Presidential chair by Mr. WINKFIELD.

The British Medical Association and the Protection of Medical Interests.—Mr. DOVYN proposed, and it was seconded and carried:

That it is to the interest of the public and of the medical profession that the Council of the British Medical Association should take power and authority to protect both the individual and collective interests of the medical profession, and that the Council be requested to take such steps as may be necessary to enable it to actively undertake these duties.

Election of Officers.—Mr. MOORE of Moreton-in-Marsh was elected President-elect. Mr. Winkfield was re-elected Treasurer, Representative on the Council, and on the Parliamentary Bills Committee. Mr. W. Lewis Morgan was re-elected Hon. Secretary. Dr. Collier, Mr. Caudwell, and Mr. Hayman were elected members of the Branch Council.

Next Annual Meeting.—Moreton-in-Marsh was selected as the place for the annual meeting in 1896.

Luncheon.—Mr. H. P. Symonds then entertained the members of the two Branches at luncheon, and was supported by Mr. Fowler of Cirencester, the President of the Gloucestershire Branch. About sixty-five members of the combined Branches were present.

President's Address.—After luncheon Mr. HORATIO SYMONDS read a paper on Antiseptic Surgery, and at the conclusion Sir HENRY ACLAND addressed the meeting.

Visits to Laboratories, &c.—The members of the Oxfordshire Branch then showed the members of the Gloucestershire Branch the various colleges, schools of laboratories, and other objects of interest in Oxford, and a most pleasant day was spent.

SOUTH-WESTERN BRANCH.

The annual meeting of this Branch was held at Tiverton, on June 26th, Dr. POWELL, of Torquay, Vice-President, in the chair. Forty-two members attended.

Installation of New President.—The minutes of the last annual meeting having been taken as read, and a cordial vote of thanks passed to the retiring President, Mr. Nettle, of Liskeard, Dr. POWELL introduced the new President, Mr. MACKENZIE, of Tiverton, who took the chair.

President's Address.—The new President delivered his inaugural address, in which he drew attention to the fact that the meeting was one of many in England at which a vote was being taken to alter considerably the constitution of the British Medical Association. At present the Association was too one-sided. They wanted the Association to become for medical men what the Incorporated Law Society was for lawyers. The medical profession was the least businesslike and the most philanthropic in the world. They were constantly giving their services, day and night, without any remuneration, until these services had come to be expected as a matter of course. The time had therefore arrived when for the benefit of all some arrangement should be made. If the proposed reform was carried out the Association, instead of numbering half the medical profession, would represent all. There was a few smaller Societies doing their best for the profession in medico-legal and other capacities. These, however were neither large enough nor powerful enough to succeed in establishing such a system of support as was anticipated to accrue from the reform of the British Medical Association which was to be proposed.—Dr. DEAS, of Exeter, in moving a vote of thanks to the President for his address, said that the British Medical Association had an immense amount of latent power which could be developed for the benefit of the profession at large. In medical defence particularly it might take up a position of great usefulness. The vote of thanks was seconded by Dr. ROLSTON, of Devonport, and carried unanimously.

Report of Council.—The report of Council stated that the Branch had increased its numbers by 16. The financial position was satisfactory. The next annual meeting would fall to be held in the Three Towns, and the Council suggested the name of Dr. Hingston, of Plymouth, as President-elect. The report was adopted.

Election of Officers.—Dr. Gordon was re-elected Honorary Secretary; Mr. Mackenzie and Dr. Gordon were elected representatives on the Council of the Association; and Dr. Gordon was elected the representative of the Branch on the Parliamentary Bills Committee.

The British Medical Association and the Protection of Medical Interests.—The HONORARY SECRETARY then submitted the following resolution:

That it is in the interest of the public and of the medical profession that the Council of the British Medical Association should take power and authority to protect both the individual and collective interests of the medical profession, and that the Council be requested to take such steps as may be necessary to enable it to actively undertake those duties.

Dr. WELSFORD, of Tiverton, seconded this resolution, and Mr. BELL, Dr. SLADE KING, and Dr. BARNES spoke in support of it. The resolution was unanimously carried.

Abuse of Charities.—It was resolved that the question of the abuse of charities be referred to the Branch Council.

Midwives Registration Bill.—The following resolution was proposed by Dr. WOODMAN:

That this Branch cannot approve the Midwives Bill now before Parliament, inasmuch as they believe that it would be not a benefit but an injury to the public.

This was seconded by Dr. ROLSTON, and carried unanimously.

Registration of Midwifery Nurses.—Dr. ROLSTON proposed that the consideration of the Bill suggested by the Parliamentary Bills Committee be postponed until a copy of it had been circulated in the BRITISH MEDICAL JOURNAL. This was seconded by Dr. SLADE KING, supported by the President, and carried unanimously.

Dinner.—After the meeting there was an excursion to Dulverton, and the members dined together in the evening at the Palmerston Hotel, Tiverton.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

The summer meeting of the Branch was held at Keith on June 26th, Professor STEPHENSON in the chair.

New Member.—Dr. P. Howie (Keith) was admitted a member of the Association and Branch.

Representative on Council.—Professor Finlay was elected representative to the General Council of the Association.

Notice of Motion.—Dr. MACKENZIE BOOTH gave notice of a motion to be brought before the next meeting of the Branch.

Dinner, etc.—A dinner followed in the Royal Hotel, the President in the chair. Various toasts were given and replied to, and a very pleasant hour was spent. In the forenoon the members drove from Keith to Gordon Castle, and Fochabers, where luncheon was served under the Duchess's tree. After viewing the castle and grounds, they returned to Keith in time for the meeting.

NORTHERN COUNTIES OF SCOTLAND BRANCH.

The annual meeting of this Branch was held at Elgin on June 26th, 1895, Dr. CRICKSHANK, of Nairn, in the chair. There was a large attendance of members.

Installation of New President.—The retiring President proposed as his successor the President-Elect, Dr. SIMPSON, of Buckie, who took the chair, and delivered an address on Physiological and Psychological Features of the Fishermen on the Banffshire Coast. He accounted for the situation of the various villages along the coast by some physical peculiarity of the coast line pertaining to the different localities—such as creeks, burns, promontories, etc. The Celtic and Scandinavian elements found in the inhabitants of the various villages were clearly discernible at the present day. The effect of environment on the different types in the way of modification of the original was shown. Intermarriage, idiocy, superstition, and their most common ailments were also dealt with. Compulsory education and the establishment of public dairies were shown to be of immense advantage to the "dwellers by the sea" in the way of producing healthy bodies and sound minds. The President was warmly thanked for his very interesting contribution.

Medical Clubs.—Dr. MUNRO MORRIS, of Inverness, proposed the following motion:

(1) That this Branch considers the action of the medical profession in Cork with reference to attendance on members of medical clubs highly commendable and deserving of support. (2) That a subcommittee of this Branch be appointed to consider the question of medical clubs, friendly societies, and medical aid societies, and to report.

Dr. Moir supported this motion in a lengthened and well-received speech, and the motion was unanimously carried and a subcommittee appointed.

New Members.—The following new members were admitted: Dr. Keay, Inverness District Asylum; Dr. Duncan, Invergordon; Dr. Kunz, Lossiemouth; and Dr. Bill, Elgin.

Election of Officers.—The following office bearers were then elected for 1895-96:—President: Dr. Simpson, Buckie. President-elect: Dr. Mackenzie, Inverness. Vice-Presidents: Drs. Cruickshank and Adam. Representative to Council and Parliamentary Bills Committee: Dr. Ogilvie Grant.

Dinner.—The members afterwards dined in the Gordon Arms Hotel.

CAMBS AND HUNTS BRANCH.

The annual meeting of this Branch was held on June 14th at Bishop Stortford, under the presidency of Dr. MORRIS.

Re-election of Officers.—Prof. Bradbury, Mr. Hough, and Mr. Gray were re-elected members of Council of Branch. Mr. Stear was re-elected Representative of the Branch on the Council of the Association. Mr. Balding was re-elected Representative of the Branch on the Parliamentary Bills Committee. Dr. Joseph Griffiths was re-elected Hon. Secretary.

Registration of Midwives.—It was resolved on the proposition of Mr. BALDING, seconded by Dr. BRADBURY:

That the Bill for the compulsory registration of midwives now before Parliament does not meet with the approval of the members of this Branch of the Association.

New Members.—The following were duly elected members

of the Branch: Dr. Lloyd Jones, Cambridge; E. Stanley Wood, I. K. Q. O. P. I., Cambridge; H. J. Hargrave, M.B. Camb., Haverhill; U. Hartley, M.R.C.S., L.S.A., Bishop Stortford; W. F. Haynes, L.R.C.P. Lond., Stanstead; O. Magoris, M.R.C.S., Gt. Shelford.

Proposed Conjoint Meeting.—It was resolved to accept the invitation of the members of the East Anglian Branch of the Association, and to join them in a combined meeting in the year 1896.

President's Address.—The President delivered a short and interesting address upon the history, antiquities, etc., of the ancient town of Bishop Stortford.

Smile Plithora.—Professor CLIFFORD ALLBUTT gave a summary of a lecture he had recently delivered on this subject. He showed how it differed from the usual forms of renal affections which not infrequently occurred in advanced years. This condition might be much benefited by the use of calomel followed by saline purgatives.—Professor BRADBURY, Dr. LATHAM and others took part in the discussion which followed.

Bichromate of Potassium in Gastric Affections.—Professor BRADBURY related seven cases in which he had tried this drug. In all it was administered in the form of capsules containing $\frac{1}{2}$ grain each; one was given on an empty stomach. Five of the cases were greatly benefited, but in two no amelioration followed. The cases presented various clinical features of chronic gastric disease. Of the unsuccessful cases one was probably pyloric cancer; another was a young woman affected with severe gastralgia. Of the two successful ones, one was a clergyman who had been under observation for years. He complained chiefly of a "feeling of rawness and soreness in the stomach." No objective signs were present. Previously he had been relieved by a mixture containing bismuth and belladonna; potassium bichromate produced no amendment. The second was that of a lady, past the menopause, who complained of severe gastralgia. Bichromate capsules failed to give relief, although a powder containing bismuth, magnesia, soda, and compound opium powder had previously done so. Professor Bradbury referred to the successful cases reported by Vulpian and Fraser, which presented similar clinical characters to his own. The explanation of the action of the bichromate, he said, was difficult. Pharmacologically it acted mainly upon nervous and epithelial structures; in large doses it was an irritant poison. The salt probably acted by stimulating the blood supply of the stomach and modifying the depressed metabolic activity of the gastric cells. Dr. Bradbury concluded by referring to the methods of administration and the possible contraindications to its use. Experimentally Gergens had produced parenchymatous nephritis, and nervous symptoms had been produced by various other observers, but hitherto no such effects had followed the therapeutic administration of the drug.

WEST SOMERSET BRANCH.

The fifty-second annual meeting of this Branch was held on July 4th, at the Gables, Stoke-under-Ham, the residence of the President-elect, Mr. Walter W. Walter.

Luncheon.—Twenty-four members, with several gentlemen not members, including the Vicar of Stoke, partook of an excellent luncheon by the kind invitation of the President-elect, before the business of the meeting commenced.

Installation of New President.—After a few remarks on his past year of office, Mr. WILCOCKS resigned the chair to Mr. W. W. Walter.

Confirmation of Minutes.—The minutes of the last meeting were read and confirmed.

Report of Council and Treasurer's Accounts.—The report of Council was read, and the Treasurer presented his accounts. The report of Council stated that an increase of members had taken place during the past year. Ten new members had joined, three old members had left the district, and one had resigned. The Branch now numbered 69 on its roll, as against 63 last year. The Treasurer's accounts, which had been audited by Mr. Rigdon, showed a credit balance to the Branch account of £7 10s. 10d. A very successful autumnal meeting was held on October 26th, when Professor Cheyne, of King's College, delivered an address on the Development of Modern Methods of Wound Treatment. At the spring meet-

ing, on March 7th, Mr. Abbott read a very instructive and interesting paper on Scoliosis and its Treatment. At the last annual meeting the question of proposed legislation for enforcing the registration of midwives was discussed, and the meeting resolved that in its opinion the plan as then proposed was not required. A Bill for "the Compulsory Registration of Midwives" was introduced into the House of Lords, which, however, had not met the approval of the Parliamentary Bills Committee of the Association. The Chairman of the said Committee, in a letter dated June 24th, had forwarded to the Branch a rival Bill which they had had drafted, entitled "A Bill to promote the better training of Women as Midwifery Nurses, and for their compulsory registration as such," with a request that it might be placed before the Branch, and that the opinion of the Branch thereon may be taken and sent to the Parliamentary Bills Committee as soon as possible. The representative of the Branch, Dr. Winterbotham, would, had he been able, have brought this matter forward in the course of the business as arranged for this day's proceedings, but he was only now convalescent from a long and dangerous illness.

Vote of Sympathy.—Resolved:

That the report of Council and the Treasurer's accounts be received and adopted; and that the Secretary be requested to write a letter to Dr. Winterbotham and convey to him an expression of the great sorrow the meeting has felt at hearing of his serious illness, and of their sincere hope that his convalescence, which they are happy to hear is progressing favourably, will soon end in complete recovery.

Election of Officers.—It was resolved (1) that W. L. Winterbotham, M.B., be the representative of the Branch on the Council of the Association and on the Parliamentary Bills Committee for the ensuing year; (2) that, of the three members of the Branch Council who retire in rotation, J. Meredith, M.D., and W. L. Winterbotham, M.B., be re-elected, and that, in the place of Mr. J. B. Cosens, who has left the district, Mr. C. E. Abbott be elected, for the ensuing year. Dr. Kelly was re-elected Secretary and Treasurer. No member being found willing to accept the office of President-elect for 1896-97, it was resolved that it be left to the Council to find a President-elect, and to arrange for the next annual meeting, and that they be also requested to arrange for an autumnal and a spring meeting as usual.

President's Address.—Mr. WALTER delivered an interesting address on his Personal Experience of the Practice of Medicine, Surgery, and Midwifery during the last Fifty Years. A short discussion followed.

Vote of Thanks.—The following resolution, having been moved and seconded, was carried by acclamation:

That the best thanks of the meeting be given to the President for his address, and also for the most kind and hospitable way in which he has received and entertained the Branch.

Communication.—Mr. MACILWAINE mentioned a case of Diphtheria treated by Antitoxin.

Registration of Midwives.—This matter was shortly discussed, and it was proposed:

That in the opinion of this meeting the Midwives Act, 1886, as in course of passage through the House of Lords is not required and should not be supported by the medical profession. If, however, legislation on the subject is found to be inevitable, then, in the opinion of this meeting a Bill on the lines of that drafted by the Parliamentary Bills Committee is to be preferred to the one before Parliament.

To this the following amendment was proposed:

That the last clause of the resolution commencing with the words "if however," be omitted.

On being put to the meeting the amendment was carried *acem.* The curtailed resolution, as follows, was then read from the chair:

That in the opinion of this meeting the Midwives Act, 1886, as in course of passage through the House of Lords is not required and should not be supported by the medical profession.

One or two speakers were averse to carrying such a resolution, but on a show of hands being taken about twenty were for it and only three against it. The resolution was therefore declared to be carried.

Entertainment.—This concluded the business. Tea on the lawn, at which Mrs. Walter and some lady friends presided, with an excursion to the Ham Hill Quarries and the Roman Camp brought a very pleasant and successful meeting to a close.

SPECIAL CORRESPONDENCE.

PARIS.

Honours for M. Roux.—The Sanitation of Match Factories.—A Commission on Foreign Medical Examinations.—Overcrowding in Flats.—General News.

At the end of last year the Municipal Council decided to give to Dr. Roux, in the name of the city of Paris, a gold medal. A few days later the General Council came to the same decision. On July 4th these medals were formally presented to Dr. Roux at the Hôtel de Ville. M. Pasteur was unable to be present on account of weak health. Dr. Roux replied to the numerous complimentary speeches by saying that he had worked under the direction of M. Pasteur and had only developed what others had done before him.

Dr. Magitot, a recognised authority on the question of phosphorism, in an excellent letter to the *Temps*, affirms that the evil results from using white phosphorus in making lucifer matches can be avoided by taking certain precautions. It is a mistake to attempt to suppress the use of white phosphorus; what ought to be suppressed is the unhealthy condition of the factories and the indifference of those who manage them. There are lucifer match factories which are perfectly healthy, where the hands are never attacked with phosphorism; whereas others are perfect hotbeds of necrosis and phosphorism. These factories, notwithstanding the ability and energy of the engineers who direct them, cannot be made healthy. The condition goes on from bad to worse, and radical measures are urgently called for. Dr. Magitot regrets that the Minister did not visit the lucifer match factories, accompanied by a competent guide; he would then have seen that these factories have become foci of disease. Few are constructed in a suitable manner; moreover, rudimentary buildings have been added, in which aération and ventilation are absent, or a mere sham. There is no arrangement for evacuating the debris, neither running water nor sewers, but in the middle of a yard these dangerous pestiferous products burn in the open, adding their deadly emanations to those of the phosphorus. The workrooms send forth clouds of poisonous phosphorus vapour sufficient to poison the whole neighbourhood. Dr. Magitot says such factories must be suppressed; the others must be remodelled.

The Minister of Public Instruction has organised a Commission to examine the value of the foreign examinations passed by students of different nationalities asking for an "equivalent," which gives them the right of being inscribed on the list of students of the Paris Medical Faculty.

The Paris flats, composed of two or three rooms, are frequently overcrowded: 14 per cent. of the population live in that unhealthy condition. On the outskirts of Paris, Passy and Batignolles are the only exceptions to the rule. This overcrowding is coincident with an increased mortality, both resulting from indigence. Nevertheless, overcrowding is more frequent in Berlin, Buda-Pesth, and St. Petersburg than in Paris.

A bust of the late Dr. Dujardin-Beaumez has, by means of subscription, been paid for and placed at the Cochin Hospital, in the court where the pavilions due to his initiative are constructed.

At Locerain a statue has been erected in honour of the late Father Damien, who devoted his life to tend the lepers at Honolulu, where he succumbed to the malady.

A statue to Boussingault was, on July 7th, placed in the courtyard of the Conservatoire des Arts et Métiers. The Minister of Agriculture was present as a substitute for the Minister of Commerce. In his speech he stated that, during half a century, Boussingault, at the Seine Sanitary Council, put in force the principles of modern sanitation. He was one of the first who fought against professional maladies, and formulated sanitary measures to be adopted by brass and lead workers and those who handle mercury and phosphorus.

MEDICAL MAGISTRATE.—Dr. A. O. Wiley, of Knarborough, has been appointed to the Commission of the Peace for the West Riding of Yorkshire.

ST. PETERSBURG.

Superstition in Siberia.—Some Examples of Longevity.—The "Flying Squads" of Oculists and the Russian Peasants.—A Russian Medical Conference.

A CASE of considerable importance was recently tried before the Governmental Court of Tomsk in Central Siberia. At this trial thirteen peasants, belonging to the district of Barnaul, in the same Government, were charged with the murder in 1892 of a man, a stranger to the district, who was taken by the peasants for "the cholera." Firm in this belief they killed him. At the trial some curious circumstances were brought out, which throw a strange light upon the mental attitude of the chief actors in this tragedy. The murder was not committed on the impulse of the moment: it was carried out deliberately and with a sort of official sanction, for the *starosta*, or elder (the peasant head of the village), though not himself taking part, sent a representative—a Kirghiz named Tchekin—to assist in the "sacrifice." The unfortunate victim was a peasant from another district, who was passing through the village of Trubatcheva. The villagers were fearing the approach of cholera and conceived that the first stranger who came was the dreaded thing itself. They imagined that he was "destroying the people and their cattle." The fact that he had a passport did not save him, and a paper found on him containing a list of the surrounding villages only confirmed the suspicions of the peasants. They dragged him a hundred fathoms from the village, two of them shot him, the others beat him with sticks, and they then buried the body in the forest. The body was subsequently exhumed, the bullet wounds found, and a number of other hideous injuries, the skull being fractured into as many as sixteen pieces. The Court found all the accused guilty; two, being under age, were sentenced to five years' and four months' hard labour; the remainder to eight years' hard labour. "Extenuating circumstances" were found in every case, and the matter will consequently be referred to the Senate for final decision. The present case is not an isolated one in the history of cholera epidemics in Russia; it could be paralleled by similar instances from the epidemic of 1832.

This country, notwithstanding the severity of its climate and other drawbacks, would seem to be not unfavourable to longevity, if one may believe the newspaper reports of certain remarkable cases. Last year attention was called to an aged Frenchman, Nicolas de Maria, who shortly afterwards died in Saratof at the age of 126. He had fought in the Napoleonic wars, and fallen a prisoner to the Russians in 1812. A little later mention was made of a Cossack named Solodof, living in the Government of Peltava, also at the age of 126. Now the cases are reported of a Russian soldier, living in Wyburg in Finland, who is said to be 122 years old; and of another Russian in Samara, Lavanli Limof, who recently died at the patriarchial age of 150. He is said to have taken part in the famous rebellion of Pugatchef in Catharine's reign. He was taken prisoner by the rebel, and then served under him; he was present at the taking of Kazan, Simbrisk, and Saratof, and at the voluntary surrender of Samara and other towns, and took part in all the exciting events of the last year of the rebellion. That great rising (the subject of one of Pushkin's most interesting prose tales) lasted from 1773 to 1775; if Edmo's age at death is correctly stated he would then be from 28 to 30 years of age. During recent years he became quite blind. Immediately after the suppression of the Pugatchef rebellion he was, of course, punished for taking part in it, and thirty years of his life he spent as a convict, and later as an exile, in Siberia, an interlude which would not, *a priori*, be regarded as conducive to long life. Since writing the above notes I observe the announcement of the death, in Thessaly, of a Greek priest at the age of 129. He is said to have kept his sight and hearing to the last.

As in each of the last three years, so in the present year, a number of "flying squads," as they are called, of oculists will be sent from St. Petersburg to various distant parts of the country by the trustees of the fund instituted in the interests of the blind by the Empress Marie Alexandrovna. This year as many as twenty "squads" will be sent, some as far as to the Siberian Government of Tomsk. In past years, there can be no doubt, this system has proved of immense

benefit to the more isolated peasantry, and is thoroughly appreciated by them. Eye diseases are extremely prevalent among them, and without some such system they would go practically untreated in many of the more sparsely inhabited Governments.

The tenth Conference of Russian Naturalists and Physicians will be held in the University of St. Vladimir, in Kiev, in August, 1898, under the presidency of Professor Theophilaktos. The last Conference was held in Moscow in 1894.

CORRESPONDENCE.

THE LANCASHIRE AND CHESHIRE BRANCH AND THE MIDWIVES BILL.

SIR.—I will briefly make what corrections and admissions seem required with reference to the above subject:

1. In proof of my entire readiness to accept the assurance of Drs. Hughes and Campbell that official signatures had been obtained to the petition, I informed them in my second letter that but for their unique set of suppressing those signatures from the BRITISH MEDICAL JOURNAL's report my first letter would have been differently worded; which is interpreted to be "striking" to the statement that they had not been obtained.

2. I know that there are official minutes of the General Medical Council, as I obtain them when required from Messrs. Spottiswoode and Co. as a bound volume at the end of the year.

3. I had not seen those for May 29th, 1895, but gave my references quite fully, namely, the BRITISH MEDICAL JOURNAL for June 1st, 1895, and for the whole of 1894. I felt quite secure in these, and my sense of security, founded on the general accuracy of the JOURNAL, would have been absolute had I known then, as I do now, that every report would undergo the vigilant scrutiny of two gentlemen who consider that "inaccuracies in dealing with an important public question are inexcusable." I am presuming that it is inaccurate to permit the omission of essential names from a published report, seen by nearly the whole profession, to remain uncorrected week after week.

4. Perhaps I shall be pardoned some surprise at having to remind my severely accurate critics, who are becoming shocked at the non-verification of references, of their omission to state that the only reference that they themselves gave by which that verification was to be effected, even if inadvertently, was entirely inaccurate.

5. I did not hear the Hon. Secretary say that the official signatures had been obtained, though I thought I heard all that was said. If I had done so, I should have felt absolutely sure that they had been obtained.

6. The only question of any importance as to the Committee's expenses had been asked by me, and satisfactorily answered at a Council meeting held immediately before the general meeting—I am, etc.,

Liverpool, July 8th.

WILLIAM CARTER.

ON DISGUIISING THE TRUTH: THE VIEWS OF A PATIENT.

SIR.—If a patient is content to accept his doctor's prescription without inquiring too closely into his opinion of the case, I do not think it is incumbent on the doctor to reveal in all cases his suspicions of grave danger; but where a patient is clamouring to know what is the matter with him it is too often the doctor's habit to return, not only evasive, but misleading replies, and I am strongly of opinion that the suspense and anxiety which result from this practice are frequently more injurious than the knowledge of the truth would be.

I must give an instance or two within my own knowledge to illustrate my meaning. A. B., a man about town, aged 30, had an epileptic seizure in which he fell and cut his head open. His usual medical adviser attended him, and to him A. B. explained the circumstances, supposing himself to have tripped over something and been stunned by his fall. That the doctor had at least some suspicions of the truth I take for granted, though I cannot be certain; but this I know, that he encouraged A. B. in his theory of the fall, and gave him

no warning as to the probable real cause, with the result that A. B. continued in his ordinary course of life, had several dangerous repetitions of his first attack (which explained fully to the doctor what was the matter, though he continued to mislead the patient on the point), and he has now been for many months under the closest medical supervision. From what I know of the man and the circumstances, I have no hesitation in saying that had he been told at first what his real malady was he would have been able to avert much unnecessary suffering.

Again, C. D. went to consult an eminent London specialist in regard to a serious ailment from which he was suffering. He was accompanied by two doctors whom he was in the habit of consulting. After hearing the particulars and examining the patient, the specialist with his two professional brethren retired to a private room, where he told them that the case was a very serious one indeed, and the ultimate recovery of the patient was very doubtful. He returned to the consulting room and told C. D. that his symptoms were favourable, and that he might count on resuming his ordinary work in six months if he took complete rest in the meantime. On this opinion C. D. built up great hopes, the inevitable shattering of which at the end of six months occasioned him, I am sure, more keen disappointment than if the truth had been judiciously broken to him at the time of the consultation.

In both these instances the patient was a man whom there was absolutely no reason to suppose lacking in courage or resolution to face the worst. The sole reason that could be given for deceiving him was that it was the rule of the profession not to take the patient into their confidence in serious cases. I am able to add that in both instances the patient, as soon as he ultimately learned the truth, began to improve; and this I must maintain to be due, at least in part, to the bitter truth bringing out the proper resistive qualities in the nature.

I wish specially to call attention to another danger.

A doctor on being called in to see a patient frequently finds him seriously ill, nursed by a wife or near relative, the patient and the nurse both attributing his condition to a severe attack of a less serious ailment than is really the case. It is my experience that in such circumstances the doctor often encourages the patient in his delusion, but tells the truth to the nurse privately; and that the nurse eventually tells the patient in a way much more abrupt and dangerous than the doctor would have used. The very fact that the doctor has concealed it from him, and that he has only learned it by working on the feelings of the nurse, increases the apprehension of the patient, and if he can obtain access to an encyclopedia or dictionary of medicine he reads the article on the disease, and is apt to imagine, from no other reason than the doctor's reticence, that he has the very worst form of the disease therein described.

I might dwell on the ethical objections to any departure from the strictest truth, but that argument would carry me too far, as I admit, at least for the purposes of this note, that there are cases where it may be necessary to conceal the truth. But this much I may say, that were the impression that doctors habitually deceive their patients for the patient's good once removed, I am certain that the general system in which doctors are held would be greatly increased.

I believe that ninety-nine doctors out of every hundred have tact enough and skill enough to break the worst news to any ordinary patient as gently as it can be done. I lay stress on this quality in doctors in contradistinction to the relatives' less judicious way of telling the truth, to which I have already adverted.

If the majority of doctors were asked the chief obstacle with which they have to contend in the treatment of disease, I believe they would name the patients' want of openness in telling all the circumstances of their case, especially where these involve anything discreditable. Is it fanciful to suggest that the patient's concealment is to some extent hastened by his belief that the doctor will not be open with him? A foolish and illogical concealing on the patient's part I admit; but if patients believed that their doctors would tell them the truth so far as known to them, I venture to say that they would themselves be more frank.

For these reasons I venture humbly to ask medical men to

consider whether it should not be made a rule of the profession to tell the patients the truth in all but very exceptional cases in which there may be fair grounds for a presumption that serious harm would be immediately caused by such a course.—I am, etc.,

J. H. T.

CASTRATION FOR ENLARGED PROSTATE.

SIR,—Mr. A. G. Faulds publishes in the *BRITISH MEDICAL JOURNAL* of May 4th a series of cases of castration for enlarged prostate, with results which are so remarkable that, as he alludes with surprise to my statistics, I cannot refrain from comment. He reports 5 cases of double castration with 4 deaths—a mortality of 80 per cent. In 3 of the 4 deaths preceded death; no other explanation of the fatality is given. In the fourth case hemiplegia, followed by death, occurred on the twenty-seventh day. In 2 other cases Mr. H. E. Clark did a single orchectomy, but both these patients died after showing mental aberration. No mention is made of a necropsy in any case. Mr. Faulds's fifth patient was alive at the end of thirty days, but showed no improvement.

Double castration in prostatics is an operation so recent that an accurate estimate of its mortality is not yet possible. It will, of course, vary greatly with the condition of the patient, especially as regards general atheroma and precedent renal infection. Guyon considers the hypertrophy of the prostate to be the result of a constitutional disorder beginning as arterial sclerosis. While I do not accept this theory of causation, the frequent association of the two conditions is a matter of common observation. It is obvious that, either with or without operation, such patients will often die from hemiplegia, and will still oftener die with symptoms associated with various degrees of cerebral degeneration, or with the mental phenomena of uræmic intoxication.

I have no wish to underrate these risks. If I have suggested an operation which will not stand the test of experience, the sooner that fact is known the better. But I must protest against such communications as the one in question being regarded as valid arguments at this time. Mr. Faulds asks, after referring to my statistics (gathered from various sources), and to the cases of Mr. Fenwick, "would it not be educative and equally important to give the details of non-successful cases?" It undoubtedly would. The details of a few carefully observed and thoroughly studied unsuccessful cases would probably be of more use just now than larger numbers with better results. But Mr. Faulds's "black list" as published does not meet the requirements.

In only two of the seven cases is the age given. In only one is the size of the prostate estimated. In two the urine is said to have contained "pus and blood;" no other urinary examination is alluded to. In only one is the amount of residual urine mentioned. The condition of the patient as to general health is not once described. In other words, nearly all the factors upon which prognosis is based have been omitted. Moreover, it is stated of these patients that "some had been relieved so far of bladder and kidney disturbance by perineal section, all with the object of minimising the immediate and remote effects of the operation." Perineal prostatotomy in such cases has a mortality of its own. It seems to me inconceivable that anyone familiar with the literature of the subject should perform it "with the object of minimising" the effects of castration. It will doubtless often be the operation of choice, and its previous performance need not necessarily prevent a later castration, but the combined operation would certainly have a higher mortality than either prostatotomy or orchectomy alone.

Double castration is one of the oldest known operations, and when performed in average subjects for local disease or injury is now generally regarded as almost without danger. Butlin estimates the proper mortality of single castration in malignant disease at about 2 per cent.

I shall shortly publish a complete statement of all the cases I have been able to collect, both successful and unsuccessful. In the meantime, I would respectfully ask that a mortality of 80 per cent. for double castration and of 100 per cent. for single castration be regarded as unusual and unnecessary even in prostatics.—I am, etc.,

Philadelphia, May 18th.

J. WILLIAM WHITE.

ABUSE OF HOSPITALS.

SIR,—You may remember that in April you inserted a letter in the *BRITISH MEDICAL JOURNAL* in which I alleged that the percentage of appointments to the out-patient department of the Gloucester Infirmary, found, on inquiry during six months, to be ineligible for free treatment, was 40.65.

It was intimated to me that my reference to the Senior Physician in that letter had held him up in an unfavourable light, so I forthwith wrote that I had no such intention, expressed my extreme regret, and apologised to him for my carelessness, and asked his nominees (Messrs. Ellis and Sumner) to send me (for publication in the *JOURNAL* if desired) the draft of such a letter as they might think would rectify the wrong which it was thought I had done.

The apology was not accepted, nor was the draft of any letter sent, but Messrs. Ellis and Sumner, at a recent meeting of the Infirmary Committee, proposed the following resolution:

The Committee having considered Mr. George Whitcombe's letter in the *BRITISH MEDICAL JOURNAL* of April 20th, 1895, resolved: "That the special mention of the Senior Physician, which places him before the medical profession in an unfavourable light, is very unfair and unjust."

The resolution was carried, and directions were given that the same should be forwarded to the *BRITISH MEDICAL JOURNAL* for publication.

For some reason Messrs. Ellis and Sumner have since requested the secretary to the infirmary not to insert the resolution in your columns, but I think that it is due to all that it should be published, leaving your readers to form their own opinion as to the weight of the words "very unfair and unjust" when used by a managing committee which considers itself attacked.

I hope that you will also allow me to set at rest a misapprehension which apparently exists in the minds of some who think that the sentence in my letter to you, in which I stated that the inquiry clearly proved certain facts, should have been preceded by the words "in my opinion." If the absence of these words have misled any of your readers I regret it, but I should have thought that a perusal of the preceding sentences would have prevented this.

The serious question, however, is: Am I right or am I wrong in the above allegation? If I have given my opinion too decidedly and in an offensive manner, I regret exceedingly that my unpremeditated want of courtesy has annoyed anyone, but the question of abuse still remains—a question, the importance of which is increasingly emphasised by the fact that the gratuitous out-patient medical relief is at Gloucester Infirmary increasing by leaps and bounds: it has increased from 6,160 (the figure on which my report was founded) in 1890 to 7,892 in 1894. This increase is, in my opinion, alarming.—I am, etc.,

Gloucester, July 2nd.

GEORGE WHITCOMBE.

METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.

SIR,—Although the remarks made by your correspondent in the *BRITISH MEDICAL JOURNAL*, June 22nd, p. 1465, about the Metropolitan Provident Medical Association appear justified by the figures taken from the annual report, I venture to assert that the state of affairs which he discloses is only a fresh illustration of the fact that the chief enemy to the general practitioner's welfare is the general practitioner himself.

The Metropolitan Provident Medical Association was founded on lines laid down by a medical subcommittee, and the medical profession has always been well represented on the Council.

But after all it is in the branches themselves that the points which most affect the interests of the general practitioner are settled. Each branch is allowed to determine what is to be the wage limit and the rate of members' contributions; and it is precisely in the branches that the medical influence is supreme. The medical officers are all *ex officio* members of the Committee of Management, and by themselves constitute in most cases an absolute majority, so that they could carry any point upon which they were agreed.

In face of the overwhelming control which the medical profession could, if they so pleased, exercise over the man-

a little inhalation of chloroform. On the night before his death he had told the local chemist that he was suffering from severe pains in the head. As he had an appointment in Edinburgh next day, he asked his housekeeper to call him early, so that he might be able to do his work at West Calder before-hand. After attempting in vain to rouse him next morning, she went into his room and found him dead, his face buried in his handkerchief, and a stoppered bottle of chloroform at his bedside.

Dr. Sloan took a full Arts course at the University of Glasgow, where he gained the Gold Medal in Senior Greek, with other distinctions, and took the degree of M.A. in 1867. In 1892, after a course in which he showed distinction in several of his classes, he graduated M.B. and C.M. at the University of Edinburgh.

After acting as assistant to Dr. Muir, of Selkirk, he went a voyage as surgeon to Calcutta. In February last he settled at West Calder. Personally Dr. Sloan possessed attractive and winning manners. He was the second son of the Rev. John M. Sloan, of the Chalmers Memorial Free Church at Edinburgh, and was 28 years of age. He was buried on July 6th in the Grange Cemetery.

PROFESSOR FRANZ VON RIED, the oldest of German surgeons, died at Jena on June 10th, aged 85. He was a pupil of Michael Jaeger, at Erlangen, and lectured in his place for some time. In 1846 Ried was appointed Professor of Surgery in the University of Jena, and this appointment he continued to hold till 1884, when he retired. His principal work is *Die Resektionen von Knochen* (Nuremberg, 1847), which in its day was a leading authority on the subject.

The death is reported of Dr. JOHN HADDEN, of Hampton Court. He graduated as M.D. R.U.I., L.R.C.S.I. and L.M. in 1864, and had practised for twenty-five years in Horncastle. Some three years ago he entered into practice in London Road, Kingston. Recently he took a house at Hampton Court for the reception of resident patients. Dr. Hadden died at St. Thomas's Hospital, to which institution he was admitted a short time previously to undergo an operation. The deceased gentleman, who was 53 years of age, leaves a widow and a family.

We regret to announce the death of Mr. JOHN DUNLOP, M.B., of Wilmslow, Cheshire, which occurred after an illness of a few days' duration at the early age of 30. Mr. Dunlop, who was much esteemed in the locality for his self-denying and compassionate bearing, succumbed to an attack of pneumonia following a chill caught in the discharge of his duties.

INDIA AND THE COLONIES.

INDIA.

THE COUNTESS OF DUFFERIN'S FUND.—The tenth annual report records the steady expansion of the work of the Countess of Dufferin's Fund. The number of patients has increased, the building of new hospitals has made steady progress, and the number of students under training has "on the whole shown a fair improvement." The number of patients treated is very considerable, amounting in 1894 to a total of 59,125, of whom 13,466 were in-patients, 50,000 out-patients treated at the hospitals, and 5,659 out-patients treated from at home. There seems to be considerable difficulty in obtaining suitable women to educate for the work. It is not limited only to persons of Native families of the higher classes to take up a medical career, but by degrees students have been attracted, so that now there are about 100 undergoing training for the various grades of assistant surgeon, hospital assistant, and nurse. It is to be noted, however, that among the whole of these are being educated in their education by Europeans. The assistant surgeons, it is true, are in many cases occupying posts of great responsibility, being in fact in charge of hospitals. It is to be noted, in the staff of completely qualified medical women, it is to be observed that five out of the twelve employed have received medical education, having been sent to England originally, with the object of securing of course the best "gradually disseminate the present progressive plan of educating lady doctors from home." The statement is also made that if the object of the association is to give the women of India the benefit of European medical skill, it would be better not to seek to encourage after cheapness.

DISPENSARIES.—Dispensaries are, says the Association of May 26th,

The Countess of Dufferin's Fund. Tenth Annual Report of the National Association for Supplying Female Medical Aid to the Women of India. (Calcutta: Office of the Superintendent of Government Printing, India, 1895. Pp. 425. 1 rupee.)

becoming more popular in the Central Provinces. Five more of these establishments were opened last year, while the total number of in-patients increased by 2,500, and of out-patients by more than 10,000. This noticeable increase can be put down to no other cause than the greater labour in which the dispensaries are held, for the general health was better than in 1893. Operations for cancer are, it may be remarked, have more than doubled within twelve months. In one country town in which this percentage was attained the Chief Commissioner asked of the civil surgeon whether so high an average could be maintained. The reply was that the surgeon knew of a hundred more cases of cancer in the immediate vicinity. "The Chief Commissioner," says the resolution, "was much impressed with the amount of curative suffering of which this answer gave evidence." The dispensaries are beginning to recognize in dispensaries a useful and profitable investment for their surplus funds. Of the increase of the number of out-patients in the total income of the dispensaries during 1894 the greater part was provided from municipal funds. The expenditure is also larger by more than Rs. 20,000, owing mainly, it is said, to an overcharge for European medicines. Private subscriptions have also increased, improved accommodation has been effected in many hospitals, whilst hospital inspection on the part of civil surgeons has also improved. These reports are largely due to the energy and ability of Surgeon Colonel Ross, late Administrative Medical Officer, Central Provinces, and now Inspector-General of Civil Hospitals, Bengal.

The Maharajah of Patiala, acting on the suggestion of Surgeon Major Owen, his medical adviser, has applied for the services of a medical officer to carry out an investigation into the fevers which prevail in his State during the rains. Surgeon Major Ronald Ross, Madras Medical Service, is the officer named by the Maharajah, and his work would be to determine certain questions respecting the mode of origin of malarial in India. He has made a special study of the subject, and he was the Parkes Memorial Prize for 1894. The Maharaj is prepared to bear all expenses connected with the investigation.

QUEENSLAND.

At a recent meeting of the Central Board of Health a draft, setting forth in popular language the decisions of the Indian Commission on Leprosy, was approved and ordered to be widely circulated.

NEW GUINEA.

THE NATIVES OF NEW GUINEA.—Professor A. C. Haddon delivered an address at the Anthropological Institute on the Natives of New Guinea, on June 11th. The ethnography of this, our largest tropical insular protectorate, is still not well known, although, thanks mainly to the labours of the wise and energetic administrator, Sir William Macgregor (who, by the way, is a Doctor of Medicine of the University of Aberdeen), much information has recently been obtained. The natives fall into two distinct groups—the true Papuan of the Fly River and Papuan Gulf districts and of the mountain ranges. These are a markedly dark, heavily-built people, with elongated skulls, most of whom wear their hair in a single mass, often called temples, and sacred ceremonies take place at the initiation of lads into manhood, masks being worn, and the bull-roarer being swung and shown to the youths. The stone club is used all over British New Guinea, but the bow and arrow is confined to the Fly River and Papuan Gulf districts. The natives of most of the coast of the south-east peninsula and of the archipelago beyond appear to belong to an immigrant stock of which the former may have come from the New Hebrides, and the latter from the Solomon Islands. They are usually lighter in colour than the true Papuans, often with brown skulls; they tattoo their bodies and live in smaller houses. There are no initiation ceremonies. The bow and arrow are replaced by the spear and the use of shields is universal. These natives have only recently learnt the use of tobacco, but they are inveterate betel chewers; the use of kava is unknown. Unlike the Papuans these people make pottery. The western Papuans are a totemistic people, and animal forms are frequently represented in their decorative art.

HOSPITAL AND DISPENSARY MANAGEMENT.

THE HOSPITAL FOR SICK CHILDREN.

A new block has been added to the north block of the Hospital for Sick Children in Great Ormond Street, Manchester, by means of which accommodation has been rendered available for 12 or more additional cases. The cost of building the wing and of furnishing and decorating the whole of the block has been borne by Miss Anna I. Jones Cohen and Miss Lucy Cohen, as a memorial to their niece, the late Hannah, Countess of Rosebery. The building, which is entirely isolated, is mainly meant for the reception of cases of diphtheria.

PRIVATE ASYLUMS IN GERMANY.—The *Daily News* correspondent, telegraphing from Berlin on July 8th, states that the private lunatic asylums of Haus Kannen, near Amelsburen, in Westphalia, belonging, like that at Munching to the Alexian brotherhood, received a surprise visit on July 8th from an official committee. The inquiry lasted two days, and is said to have yielded such remarkable results that the provincial administration is already considering the advisability of either buying the asylum or building a new one, to be placed under medical supervision and lay guardians. Gross defects were disclosed in the sanitary arrangements.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

VITAL STATISTICS OF LONDON SANITARY DISTRICTS DURING THE SECOND QUARTER OF 1895.

In the accompanying tables will be found summarized the vital and mortal statistics of the last three sanitary areas of the metropolis, based upon the Registrar General's returns for the second or spring quarter of the current year. The mortality figures in the table relate to the deaths of persons actually belonging to the various sanitary areas, and are the result of a complete system of distribution of deaths occurring in the institutions of London among the various sanitary areas in which the patients had previously resided.

During the months registered in London during the three months ending June last were 22,456 persons, at an annual rate of 30.5 per 1,000 of the population, compared at 4,356 persons in the middle of this year; this rate properly corresponded with the mean rate in the second quarters of the five preceding years (1889-94). The birth-rates during the period under notice in the various sanitary areas varied, as usual, wide variations, owing principally to the differences in sex and age distribution of the population. In Kensington, St. George Hanover Square, Hampstead, Stoke Newington, St. Martin in the Fields, and London City the birth-rates were considerably below the average, while in St. Luke, Bethnal Green, Whitechapel, St. George in the East, Mile End Old Town, St. Olave Southwark, and Rotherhithe the birth-rates showed a marked excess.

The 17,550 deaths of persons belonging to London registered during the quarter under notice were equal to an annual rate of 18.3 per 1,000; this death-rate was below that in the corresponding period of any year on record. During the June quarters of the ten preceding years, 1885-94, the

mean death-rate was 18.3 per 1,000. The lowest death-rates last quarter in the various sanitary areas were 10.4 in Hampstead, 11.0 in Stoke Newington and in Lewisham (excluding Penge), 11.4 in Wandsworth, 12.7 in Lee, 12.8 in St. James Westminster, and 12.0 in Hammersmith; the highest rates were 20.8 in Poplar, 20.9 in Newington, 21.4 in St. George Southwark, 23.6 in Strand, 24.2 in Limehouse, 24.9 in St. Luke, and 25.4 in St. George in the East. During the quarter under notice 2,011 deaths were referred to the principal zymotic diseases in London; of these 543 resulted from measles, 445 from whooping-cough, 220 from diphtheria, 314 from diarrhoea, 106 from scarlet fever, 51 from different forms of "fever" (including 1 from typhus, 16 from enteric fever, and 2 from ill-defined forms of continued fever), and 3 from small-pox. These 2,011 deaths were equal to an annual rate of 1.8 per 1,000, which was below that in the June quarter of any year on record, and 0.8 per 1,000 below the mean zymotic death-rate in the corresponding periods of the ten preceding years. The lowest zymotic death-rates during last quarter in the various sanitary areas were 0.3 in Lee, 0.5 in Hampstead and in St. Olave Southwark, 0.7 in Wandsworth, 0.8 in Kensington, and 0.9 in St. James Westminster, in Strand, and in Lewisham; while the rates ranged upwards to 2.5 in Mile End Old Town and in Whitechapel, 2.7 in Shoreditch, 3.9 in Poplar, 4.5 in St. Luke, 5.0 in Limehouse, and 5.6 in St. George in the East.

Three deaths from small-pox of persons belonging to London were registered during the three months ending June last, of which 1 belonged to Hammersmith, 1 to St. Giles, and 1 to Rotherhithe sanitary areas. Measles showed the highest proportional fatality in St. Luke, Shoreditch, Whitechapel, St. George in the East, Limehouse, Mile End Old Town, Poplar, and Battersea; scarlet fever in Hackney, St. George in the East, Limehouse, and Rotherhithe; diphtheria in St. Giles, Bethnal Green, Whitechapel, St. George in the East, Limehouse, Mile End Old Town, Poplar, Camberwell, and Greenwich; whooping-cough in Clerkenwell, Shoreditch, St. George in the East, Limehouse, St. Saviour Southwark, St. George Southwark, and Newington; and "fever" in London City and Plumstead sanitary areas.

Analysis of the Vital and Mortal Statistics of the Sanitary Districts of the Metropolis, after Distribution of Deaths occurring in Public Institutions, during the Second Quarter of 1895.

During the quarter ending June last 1,945 deaths from phthisis were registered in London, equal to an annual rate of 1.8 per 1,000. Among the various sanitary areas the lowest per 1,000 death-rates were recorded in Paddington, Kensington, Marylebone, Hampstead, Islington, Stoke Newington, and Lewisham; the highest rate in St. Giles, St. Martin-in-the-Fields, Strand, Whitechapel, St. Saviour Southwark, and St. George Southwark.

Infant mortality in London last quarter, measured by the proportion of deaths under one year of age to registered births, was equal to 130 per 1,000; this rate almost corresponded with the mean rate in the June quarters of the ten preceding years. Among the various sanitary areas the rates of infant mortality were lowest in St. James Westminster, Marylebone, Hampstead, Stoke Newington, Bethnal Green, Wandsworth, Lewisham, and Plumstead, while they showed the largest excess in St. Martin-in-the-Fields, Shoreditch, Lambeth, St. Saviour Southwark, St. George Southwark, Newington, and St. Olave Southwark.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns, including London, 6,420 births and 3,664 deaths were registered during the week ending Saturday, July 6th. The annual rate of mortality in these towns, which had increased from 12.4 to 12.7 per 1,000 in the three preceding weeks, further rose last week to 12.8. The rates in the several towns ranged from 9.1 in Croydon, 10.9 in Brighton, and 10.6 in Nottingham, to 21.4 in Bradford, 21.8 in Salford, and 24.4 in Liverpool. In the thirty-two provincial towns the mean death rate was 17.2 per 1,000, and was 0.5 below the rate recorded in London, which was 15.0 per 1,000. The zymotic death-rate in the thirty-three towns averaged 2.8 per 1,000, in London the rate was equal to 2.0 per 1,000, while it averaged 2.7 in the thirty-two provincial towns, and was highest in West Ham, Leicester, and Wolverhampton. Measles caused a death-rate of 1.6 in Manchester, 1.9 in Blackburn, and 2.0 in West Ham; whooping-cough of 1.1 in Sunderland and 1.3 in Bolton; and diphtheria of 2.0 in London, 2.3 in Cardiff and in Salford, 4.3 in Wolverhampton, and 5.1 in Leicester. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 71 deaths from diphtheria in the thirty-three towns included 53 in London, 4 in West Ham, 3 in Salford, and 3 in Leeds. Four fatal cases of small-pox were registered in Oldham, 3 in London, and 1 in Liverpool, but not one in any other of the thirty-two provincial towns. There were 62 small-pox patients under treatment in the Metropolitan Asylums Hospitals and in the Highgate Small-pox Hospital on Saturday last, July 6th, against 19, 32, and 34 at the end of the three preceding weeks; 17 new cases were admitted during the week, against 2, 8, and 20 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had been 1,697, 1,732, and 1,594 at the end of the three preceding weeks, had further increased to 2,044 on Saturday last, July 6th. 311 new cases were admitted during the week, against 150, 251, and 319 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

During the week ending Saturday last, July 6th, 935 births and 560 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had been 10.4 and 10.2 per 1,000 in the two preceding weeks, rose again to 10.4 last week, and was 1.9 per 1,000 above the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 11.7 in Perth to 25.1 in Greenock. The zymotic death-rate in these towns averaged 3.4 per 1,000, the highest rates being recorded in Glasgow and Paisley. The 286 deaths registered in Glasgow included 4 from diphtheria, 7 from measles, 1 from scarlet fever, 2 from diphtheria, and 1 from small-pox. Five fatal cases of measles were recorded in Paisley.

LUNACY CASES IN WORKHOUSE HOSPITALS.

"Junior" does not state his case clearly. Probably he refers to a medical certificate in support of an application to a justice for an order for detention of a lunatic in a workhouse. If so, there is nothing to prevent the "medical certificate under the hand of a medical practitioner not being an officer of the workhouse" being signed by "Junior's" deputy. Inasmuch as said deputy is not an officer of the workhouse. This certificate must be in Form A of Schedule 2 of the Act 53 and 54 Vict.

INCREASE OF SALARY FOR WORKHOUSE MEDICAL OFFICER.

From the report in the *Derbyshire Times* we learn that at a recent meeting of the Keeper Board of Guardians, at which the question of an advance of salary to Dr. Allen, the medical officer of the workhouse was fully considered on the presentation of a report made by a subcommittee that an increase of salary of £50 per annum should be awarded, there appears to have been most strenuous opposition by several of the guardians, but notwithstanding that the report of the committee was adopted by resolution of the majority. We are unable to see that there was any reasonable ground for opposing this report. The decision must be highly satisfactory to Dr. Allen and his supporters.

THE WEXFORD GUARDIANS AND THE LUNATIC.

The letter recently circulated through the press on the state of the Irish workhouse was discussed by the advice Board at its last meeting, with the result that a committee was appointed to confer with the medical officer about the condition of the lunatics in the workhouse. Some of the guardians were of the opinion that much more should be done for these poor afflicted creatures, and that in many cases the element of appropriate treatment and the surroundings of the workhouse should be tested to ascertain and confirm the condition of mental instability, which in more favourable circumstances might have been ascertained. This question is of extreme importance, and we trust that the action of this Board may have far-reaching results.

MEDICAL NEWS.

SOCIETY FOR THE STUDY OF INSANITY.—At a meeting on July 4th, Dr. Norman Kerr in the chair, Dr. A. Mansfield Holmes, of Denver, U.S.A., gave an interesting account of the records of the Daildorf Asylum at Berlin. The proportion of cases of hereditary insanity to acquired insanity was from 2 to 1 to 3 to 1 in different periods. Of the former group, 9 per cent. of the cases were directly traced to drunken parents; of the latter, 10 per cent. The Director, Dr. Rust, placed heredity as the chief cause of insanity, and alcoholism the second. His conclusions were that alcohol excited to acquired insanity and produced hereditary insanity by bringing about organic changes in the ancestor which are transmitted to the children in the form of predisposition. Periodical drinking to excess was more detrimental to the individual parent and habitual to the offspring. Dr. Kerr, with reference to the objections urged in the House of Lords as to undue interference with the liberty of the subject and other abuses of a law for the restraint of habitual drunkards, said there would be no difficulty, by definition, ample inspection, power of appeal, etc., in so safeguarding the interests of habitual drunkards as to render any such abuse practically impossible.

The first annual meeting of the Registered Nurses' Society (269, Regent Street, London) was held by the kind invitation of the Duke and Duchess of Abercorn at Hampden House on July 6th. The chair was taken by Dr. Bedford Fenwick, Treasurer of the Society, and the report of the Committee showed that the Society has achieved a marked success in its first year of working. It was formed in order to enable the public to obtain the services of registered trained nurses, it being an essential condition of membership that every nurse must have worked for at least three years in hospitals, and must possess the highest professional qualifications and personal character. The nurses obtain their entire earnings, less a deduction of 7½ per cent., to cover the expenses of management. That the Society has met a public want is evident from the fact that more applications for nurses have been made to the Society than it could supply. That the sixteen senior nurses on the average have received £111 12s. for an average of fifty-one weeks' work is conclusive proof of the benefits of the Society to the nurses themselves. The report of the Committee, and votes of thanks to Mrs. Bedford Fenwick, who founded the Society, and has since acted as its Honorary Superintendent, and to the Duke and Duchess of Abercorn for their hospitality, were carried by acclamation.

MEDICAL VACANCIES.

The following vacancies are announced:

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon; dentistry qualified. Salary, £150 per annum, with an allowance of £20 per annum for cab hire, furnished rooms, fire, lights, and attendance. Applications to Alex. Forrest, Secretary, by July 15th.

BOROUGH OF WEST HAM.—Medical Superintendent for the Borough Hospital for Infectious Diseases at Plaistow. Salary, £200 per annum, with annual increment of £10 up to £250, with apartment in residence, and washing. Not less than 25 years of age. Applications, on forms provided, to be sent to F. E. Hillery, Town Clerk, Town Hall, West Ham, E., by July 23rd.

BRADFORD INFIRMARY AND DISPENSARY.—Honorary Physician. Applications to the Secretary by July 20th.

BRITISH INSTITUTE OF PREVENTIVE MEDICINE.—Assistant Bacteriologist in the Antisepsis Department. Salary, £200 a year. Applications to the Director by July 20th.

CANCER HOSPITAL (FREE). Fulham Road, S.W.—House-Surgeon: Appointment for six months. Salary at the rate of £20 per annum, with board and residence. Applications to the Secretary by July 15th.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Resident Medical Officer, doubly qualified. Salary, £100 per annum, with board, etc. Applications to the Secretary by July 10th.

CHICHESTER INFIRMARY.—House-Surgeon. Salary, £20 per annum, with board, lodging, and washing. Applications to the Secretary by August 10th.

COUNTY ASYLUM, Gloucester.—Third Assistant Medical Officer, unmarried, doubly qualified, and not over 35 years of age. Salary, £200 per annum, with board and attendance, lodging, and washing. Applications to the Medical Superintendent by July 15th.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Resident Assistant House-Surgeon. Appointment for six months. Salary, £15, board, inclusive of beer, wines, and spirits, residence, washing, and attendance. Applications to the Secretary by July 20th.

DROITWICH UNION.—Medical Officer for the Ombersley Medical District, must reside in the district. Salary, £200 per annum, with such extra fees as allowed by the Local Government Board. Applications to Arthur James Bearcroft, Clerk, Boardroom, Droitwich, by July 15th.

FLINTSHIRE DISPENSARY.—Resident House-Surgeon. Salary, £120 a year, with furnished house, rent and taxes free, also coal, light, water, and cleaning, or to his credit the sum of £20 per annum. A knowledge of Welsh desirable. Applications to Thomas Thomas, Secretary, Board Room, Baginbun Street, Holywell, N. Wales, by July 15th.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway Road, N.—Junior House-Surgeon. Appointment for six months. Board, lodging, and laundry provided. Applications, on forms provided, to be sent to Lewis H. Ginton Kerr, Secretary, by July 20th.

GUY'S HOSPITAL MEDICAL SCHOOL.—Lecturer on Public Health. Applications to the Treasurer, Counting House, Guy's Hospital, S.E., by July 20th.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident Assistant Physician. Applications to the Secretary by July 15th.

HOSPITAL FOR WOMEN, Soho Square.—Non-Resident House-Physician. Appointment for three months. Applications to the Secretary by July 21st.

NATIONAL SANATORIUM FOR CONSUMPTION AND DISEASES OF THE CHEST, Bournemouth.—Resident Medical Officer. Salary, £20 per annum, with board, lodging, and washing. Applications to the Secretary by July 20th.

POPLAR HOSPITAL FOR ACCIDENTS.—Senior Assistant House-Surgeon. Salary, £80 per annum, with board and lodging. Applications to the House Governor by July 10th.

QUEEN'S JUBILEE HOSPITAL, Earl's Court.—Surgeon. Applications to the Secretary by July 14th.

ROYAL VICTORIA HOSPITAL, Bournemouth.—House-Surgeon and Secretary. Salary, £100 per annum, with board. Appointment for two years. Applications to the Chairman of the Committee by July 15th.

HALFORD UNION INFIRMARY, Hope, near Eccles.—Assistant Medical Officer; doubly qualified. Salary, £150 per annum, with furnished apartments in the infirmary. Applications, endorsed "Assistant Medical Officer," to T. H. Bagshaw, Clerk to the Guardians, Union Office, Eccles New Road, Salford, by July 20th.

SHEFFIELD GENERAL INFIRMARY.—House-Surgeon and Senior Assistant House-Surgeon, doubly qualified. Salary for the former, £120 per annum, with a prospective advance of £10 per year for the second and third years; and for the latter £80 per annum, with board, lodging, and washing. Applications to the Medical Staff of the Sheffield General Infirmary, to the care of the Secretary, by July 15th. The election will take place on July 20th.

STOKPORT INFIRMARY.—Junior Assistant House-Surgeon. Appointment for six months. Board and residence provided, and £10 after six months' satisfactory service. Applications to Major C. Tyler, Secretary, by July 15th.

STROUD GENERAL HOSPITAL.—House-Surgeon; doubly qualified. Salary, £80 per annum, with board, lodging, and washing. Applications to the Honorary Secretary, G. J. Holloway, the Hospital, Stroud, by July 17th.

SUFFOLK GENERAL HOSPITAL, Bury St. Edmunds.—House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications to Henry Bonner, Secretary, by July 15th.

UNIVERSITY OF GLASGOW.—Two Examiners for Degrees in Medicine to Examine in Chemistry and Materia Medica respectively. Applications to Alan E. Chapman, Secretary of the Glasgow University Court, 94, West Regent Street, Glasgow, by July 20th.

YORK DISPENSARY.—Resident Obstetric House-Surgeon; unmarried. Salary, £200 per annum, with furnished apartments, coals, and gas. Applications to Mr. W. Draper, De Grey House, York, by July 20th.

MEDICAL APPOINTMENTS.

BAILEY, Thomas R., M.D. Edin., reappointed Medical Officer of Health to the Devon District Council.

BALLANTYNE, J. W., M.D., F.R.C.P.E., F.R.S. Edin., appointed Examiner in Midwifery in the University of Aberdeen.

BRIDGES, Ernest C., M.B., B.S. Durh., M.R.C.S., L.R.C.P., appointed House-Surgeon to the Great Northern Central Hospital.

CHARPENTIER, A., M.D. Durh., appointed Outdoor Medical Officer for the Uxbridge District of the Uxbridge Union.

CHRISTMAS, Charles Denn, M.D. Brux., M.R.C.S., L.R.C.P. Lond., appointed Medical Officer for the Streatham District of the Clapham Union.

GARSTANG, T. W. H., B.A. Oxon, M.R.C.S., appointed Medical Officer of Health to the Knutsford Urban District Council.

GIDLEY, G. G., L.R.C.P. Lond., M.R.C.S., appointed Medical Officer for the Colmington and Knollsbridge District of the Tiverton Union, *vice* J. H. Lloyd, L.R.C.P. Edin., M.R.C.S. Eng., resigned.

GOODMAN, Godfrey, L.R.C.P.I., L.R.C.S.I., L.M.R.C.P., L.M., appointed Medical Officer of Health to the Rural Sanitary District of the District Council, Brigg Union, *vice* Mr. Moxon, M.R.C.S., resigned.

GOODMAN, W. H., L.D.S.R.C.S. Eng., appointed Surgeon to the Devon and Exeter Dental Hospital, *vice* J. A. Mallart, resigned.

GREIG, W. C., M.B. and C.M. Edin., appointed Hon. Physician to H.B.M.'s Legation at Tangier.

HALPIN, J. E., L.R.C.S.I., L. and L.M. K.Q.C.P.I., appointed Public Vaccinator for Fifth District, Mansfield Union, *vice* H. Parry Jones.

HENDRIKS, C.M., M.B. Durh., M.R.C.S. Eng., reappointed Medical Officer for the Stoke Lyne District of the Leicester Union.

HICHENS, F., M.D. Lond., M.R.C.S., D.P.H., reappointed Medical Officer of Health for the Redruth Urban District.

HINES, Mr. J. C., appointed Medical Officer for the Burwash District of the Titchmarsh Union.

JOHNSTON, E., M.B., appointed Medical Officer for the Clayton District of the Preswath Union.

JONES, Dr., appointed Medical Officer for the Grange-town District of the Cardiff Union.

KELLY, Charles, M.D., F.R.C.P. Lond., M.R.C.S., reappointed Medical Officer of Health to the Midhurst Rural District Council.

MINTNER, Dr., appointed Medical Officer of the Workhouse and for the Uxbridge District of the Uxbridge Union, *vice* William Rayner, M.R.C.S. Eng., deceased.

MUDOR, Z. H., L.R.C.P. Lond., M.R.C.S. Eng., appointed Medical Officer of Health to the Melksham Urban District Council, *vice* W. F. Cleaver, L.R.C.P. Lond., M.R.C.S. Eng., resigned.

NAIRN, R. W., M.B., C.M. Glasg., appointed Medical Officer for the Farnsfield District of the Southwell Union, *vice* G. Y. Polson, M.B., C.M. Edin., resigned.

PERMEWAN, W., M.D. Lond., F.R.C.S. Eng., appointed Honorary Laryngologist to the Royal Southern Hospital, Liverpool.

PHILLIPS, Edgar V., M.R.C.S. Eng., L.R.C.P. Lond., D.P.H.R.C.S.I., appointed Medical Officer and Public Vaccinator to the No. 2 District, Market Harborough Union; Medical Officer, Market Harborough Rural Sanitary District; and Medical Officer of Health, Orsden Rural Sanitary District, *vice* Thomas Macanay, resigned.

RHIND, Thomas, M.R.C.S. Eng., L.R.C.P. Lond., appointed Medical Officer and Public Vaccinator No. 1 Western District, Billesdon Union, *vice* E. V. Phillips, resigned.

SELBY, Edmond Wallace, M.B., B.S. Lond., F.R.C.S. Eng., appointed Honorary Surgeon to the Doncaster General Infirmary and Dispensary.

SEWILL, J. Sefton, M.R.C.S., L.R.C.P., L.D.S., appointed Dental Surgeon to the St. Marylebone General Dispensary, Westcock Street, W.

SMITH, Dr. T., appointed Medical Officer for the Hampford Speke District of the St. Thomas Union, *vice* A. A. McKelth, M.B., C.M. Glasg., resigned.

STMONDS, Charles J., M.B., M.D. Lond., F.R.C.S. Eng., appointed Consulting Surgeon to the Stockwell Orphanage, *vice* Arthur E. Durham, F.R.C.S., deceased.

VEALE, F. J. de Coverly, M.B., Ch.B. Vict., appointed Assistant Medical Officer at the County Asylum, Lancaster.

DIARY FOR NEXT WEEK.

TUESDAY.

THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 2 P.M., Lecture at 4.

WEDNESDAY.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C., 3 P.M.—Lecture by Dr. Gowers.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

CARTER.—At Scarborough, on the 3rd inst., the wife of Deputy Surgeon-General H. Vandyke Carter, M.D., Q.H.S., of a daughter.

RICE.—On the 5th inst., at 5, Clarence Terrace, Leamington Spa, the wife of Bernard Rice, M.D. Lond., of a son.

SILLAR.—At 46, George Square, Edinburgh, on July 2nd, the wife of W. Cameron Sillar, M.B., of a son.

MARRIAGE.

LAWES-LUMBY.—On June 11th, at the Parish Church, Grantham, by the Rev. Dr. Perowne, Master of Corpus Christi College, Cambridge, assisted by the Rev. E. T. S. Carr, President and Fellow of St. Catharine's College; the Rev. C. E. Graves, Fellow and Tutor of St. John's College; and the Rev. E. Godfrey, Vicar of the parish, Cathbert Unparishville Laws, M.B., M.R.C.S., to Grace Margaret, daughter of the Rev. Dr. Lumby, Lady Margaret Professor of Divinity in the University of Cambridge.

DEATHS.

DAVIES.—On June 16th, Joyce Caroline, the dearly loved and only daughter of Arthur Temper and Alice Davies, 28, Finsbury Square.

SCATLIF.—On the 10th of June, at Macaulay House, Macaulay Road, Clapham Common, Harriet Scatliff, aged 70, the devoted wife of the late J. P. Scatliff, M.D., formerly of 132, Sloane Street, and Clapham Common.

SMITH.—On the 4th inst., at 19, Harley Street, W., Gertrude Mary Heywood, eldest daughter of Heywood Smith, M.D., aged nearly 24.

STYLMETER.—June 25th, at the Court House, Trowbridge, Wiltshire, George Mairis Sylvester, M.R.C.S., in his 75th year.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MONDAY MORNING ON WEDNESDAY. THE CHANCE CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 42, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the office, 42, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 42, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

IN ORDER to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUESTIONS.

MEMBER wishes to know what will decolorize carbolic acid and decolorize chromic acid without interfering with their antiseptic properties.

M.B. has a patient residing in the North of England who has been suffering from influenza in the winter, with a troublesome cough which has persisted for several months. It has now entirely gone, but left portions of the lung weakened. He would like to know the most suitable place for her to reside in the South of England during next winter, where she would not be confined to the house, as would be the case in the North.

TREATMENT OF UNDESCENDED TESTICLE, ETC.

PLYMOUTH writes: I have a patient—a boy, aged 12—who has right congenital hydrocele with a rather large inguinal ring and a left testicle retained in the inguinal canal. The treatment that suggests itself to me is a truss for the right side and a horse-shoe protective pad for the left retained testicle. Will any reader who has had experience of a similar case give an opinion on the case?

ANSWERS.

C. W. M.—Our correspondent should consult a general practitioner.

M. H.—A slight varicocele would not necessarily disqualify a candidate for the Royal Navy, but no definite opinion in any individual case could be expressed except by the medical examiners.

SEMINAR COURSES IN BACTERIOLOGY.

I.M.S.—The London Post-Graduate Course usually includes a series of lectures on bacteriology, each of which is followed by practical work in the bacteriological laboratory of King's College. Full particulars may be obtained from Dr. Fletcher Little, 32, Hoxley Street.

THE STRAIGHTENING OF ANKLYSED KNEES.

E. E. Williams writes, in reply to X., to report two of his cases suffering from the effects of rheumatoid arthritis in the knees. In one patient one knee affected had become fixed and anklysed by fibrous adhesions, this has been successfully straightened with a Thomas's knee splint in a period of four weeks by six lightening of bandages. Opium was given to allay most of the severe pain after each forcible stretching of the knee. The patient can now stand quite straight, and is commencing to walk without support. In the other case both knees are affected, and have been successfully straightened by the same process, but the patient has not recovered sufficiently yet to be up. This method of straightening anklysed knees is fully treated in *Contributions to Orthopaedic Surgery*, by Robert Jones, F.R.C.S.E., of Liverpool, and John Kidson, M.A., M.D. Chicago.

DER DEUTSCHER ARZTEVEREIN.

W.—The Deutscher Aerztetag, or Diet of German Physicians, consists of the deputies of the various associations of practitioners throughout the empire, and may fairly be considered to express the opinions generally prevailing on the various topics under discussion. Any medical association numbering at least twenty-five members acquires by entering the Aerztetagsverband, or Union of Medical Associations, the right to depute a delegate, with the power of voting, to the yearly Convention, the Aerztetag. At the meeting at Elberach on June 28th and 29th, which was the twenty-third annual assembly, 117 delegates, representing some 11,000 members of the medical profession, were present. A council is elected each time for the management of the affairs in general and the editing of the *Deutsches Aerztblatt*, the official organ of the Association. In reality this council is almost a permanent one, as the same members, with few exceptions, are re-elected by a great majority. Thus Dr. Graf, for the time being Vice-President of the

Prussian Landtag, has for several years occupied the post of President of the Aerztetag. Executive powers are not entrusted to this assembly, but, by expressing the views and wishes of the profession at large, it has repeatedly proved of much real value to members of high importance. The Aerztetagsverband is connected with the Aerztische Verein, or Chambers of Physicians, which were instituted under the administration of the former Minister, von Cancelli, for each one of the various provinces. These boards consist of a certain number of members chosen by direct ballot in each district by all practitioners therein resident, irrespective of whether they belong to an association or not. Their duties and prerogatives are very much the same in their particular sphere as those of the Aerztetag for the whole country; each is a sort of medical assembly without executive powers.

NOTES, LETTERS, ETC.

ERRATUM.—Dr. Charles Porter (Sheepskin) writes: I find there is a clerical error in the article on Metropathian Water Supply, published at p. 168 of the BRITISH MEDICAL JOURNAL of June 2nd, in paragraph 4, beginning "Judged by the relatively," the words "carbon" and "nitrogen" ought, of course, to be transposed.

THE HOMES OF MEDICAL MEN.

THE annual report of the Society of Arts just issued for 1905-6 has the following paragraph: "The sixth and last source of the session consisted of two lectures by Mr. Ernest Hart upon a subject which he has made his own, that of 'Japanese Art Industries.' Mr. Hart dealt with his subject from a more commercial point of view than he adopted in his previous lectures on 'Japanese Art Work,' in 1904. He pointed out that much of the most modern Japanese work is of very high artistic value, and will bear comparison with the productions of the old Japanese masters, and indicated the direction in which he thought Japanese artists should work if they desired to supply the European market. The lectures were finely illustrated from Mr. Hart's own collection."

THE FUNCTION OF THE SUPRARENAL BODIES.

DR. C. DANIELS (British Guiana Medical Service) writes: In the recent Goulstonian Lectures on the Suprarenal Bodies, by Dr. Rolleston, doubt is thrown on the theory that these organs remove pigment from the blood. As bearing on this, it may be of some importance to point out that, whilst in acute malarial pigment is found in these organs in common with all others, it is not so to any great extent, and is chiefly in the capillaries. No such accumulation as always takes place in the spleen and liver have I ever seen. Further, shortly after acute malarial there is none to be found in them, nor is any evidence of it found in cases where the spleen shows old malarial pigmentation. Further, in ankylostomiasis, whilst the liver and other organs give pigimentary evidence of hemolysis, there is no increased pigmentation of these organs. My standard of comparison in both is that of the coloured races. In connection with the hemorrhages in the suprarenals in the newly-born in a case I had at Queen Charlotte's Hospital in 1904, and in two I have seen here, there was no laceration of the organs, and the blood was contained in the meshes of trabeculae, which were unruptured in an orderly manner, not suggestive of violence.

"LOCAL CANDIDATES AND THE PUBLIC ADVERTISEMENT OF VACANCIES."

ANOTHER D. P. H. writes: Like "D. P. H.," I have during the past two months been at considerable expense in having testimonials printed for appointments which in every instance have been filled by a local man. Only last week I was fortunate enough to be one of three selected candidates, the other two being local men, sons of aldermen of the town. Naturally when I was asked to meet the guardians I thought I was surely in the "running," but imagine my disgust when the voting came out 22, 10, and 1, the last one being given to me (I admire one who has the "backbone" to vote according to his convictions). Such treatment as this is, I hold, a gross insult. When it was so cut and dried why put an outsider to such inconvenience, especially to be insulted? In addition to the insult, I was very much amazed next day to see the account of the meeting, with voting, published in a newspaper local paper which has a wide circulation in the district where I am practising. Guardians and other electing bodies should remember that candidates are not devoid of some sense of feeling, and should bear in mind the good old motto, "Do unto others as you would they should do unto you."

IS CARBOLIC ACID A SUITABLE AGENT TO BE EMPLOYED IN CARRYING OUT THE ANTISEPTIC TREATMENT OF ENTERIC FEVER?

BURGON LIEUTENANT-COLONEL R. H. QUILL, A.M.S., writes: In late years the soundness of the principle of treating cases of enteric by producing intestinal antiseptics has been steadily gaining ground, and among the numerous antiseptic agents employed for this purpose in view pure carbolic acid has occupied a foremost place. For the past three years I have used this acid largely in the treatment of enteric fever, and with very gratifying results. Certain theoretical considerations, however, have made me ask myself, has carbolic acid been really responsible for the good effects which I have observed to follow its use in enteric fever?

While lately reading in the new edition of Quain's *Textbook of Medicine* the article on Micro-organisms, I found that Chamberland and Wilder have experimentally proved that the enteric bacilli actually develop in the presence of carbolic acid, and that by its aid the enteric bacillus can be separated from many other putrefactive organisms which may happen to exist in the same medium, the latter being killed while the former developed.

I am well aware that carbolic acid is primarily given in enteric fever in order to antiseptize, if not altogether destroy, the septic processes taking place in the intestinal canal; but our antiseptic agent may do more than this—it may be able to follow the bacteria into the blood. If it does, and the experiment is referred to are reliable, instead of producing an antiseptic effect in the blood, it may have a truly opposite effect, encouraging the growth of the septic bacteria. I may

be answered that my fears are groundless owing to the minute quantity of the antiseptic which enters the blood. Is that the case?

In treating a case of enteric fever of any severity I am in the habit of giving salicylate of soda, a mixture of pure salicylic acid of various strengths every second hour up to ten doses, and in many instances have continued doing so for ten days, or even longer, with, I am satisfied, unquestionable benefit to the patient. I think it is reasonable to assume that the daily administration for ten days or more of half a drachm of pure salicylic acid will result in a considerable quantity of the acid being absorbed into the blood. Granting this, it ought, if the experiments of Chauveau and Vidal be correct, to produce an increase and not a diminution of the enteric bacilli in the circulation.

THE DENTAL PROFESSION.

DR. J. B. BROWN (Barnstaple) writes: From my own experience, as well as that of my friends, who are able to judge as to unqualified dental practice in some of our Lancashire towns, the statements of Dr. Hugh Woods are amply justified. Mr. Storor Bennett's statement may be perfectly correct by what he knows of the dental practice in Barnstaple Square and its surroundings. I know of unregistered dentists who have far larger practices than registered men. There is nothing to prevent anyone practising dentistry so long as he avoids the words dentist, dental surgeon, etc. This is well known, and is acted upon in the North of England.

LETTERS, COMMUNICATIONS, ETC., have been received from:

(A) Mr. P. E. Adams, London; Dr. F. J. Allen, Birmingham; G. W. Anonim, M.B., Gloucester; Mr. S. E. Atkins, Axminster; Professor Atfield, Watford; Anti-Quack; Messrs. Arthur and Co., London; Mr. D. SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	2s 4 0
Each additional line	0 0 6
A whole column	1 17 6
A page	5 5 0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage-stamps.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Reçues* addressed either in initials or numbers.

A DEMONSTRATION ON ANAL FISSURE OR ULCER

In the Out-Patient Department St. Bartholomew's Hospital.

By HARRISON CRIPPS, F.R.C.S.,

Assistant Surgeon to the Hospital.

GENTLEMEN,—As we have now finished seeing our out-patients, I will take the opportunity of briefly referring to the two rectal cases we have examined, for they afford excellent examples of one of the commonest forms of rectal trouble, namely, anal ulcer or fissure.

When a patient complains of rectal disorder, it is possible by a few selected questions to form a fairly accurate view as to the nature of the trouble. Of course a positive diagnosis can only be arrived at after a careful and thorough examination of the part. In calling your attention to the questions that I asked the patient, you must not for a moment be led into the error of supposing that it would be right to treat any rectal disorder unless the diagnosis had been confirmed by a physical examination. Patients with rectal disease nearly always assert that they are suffering from piles, and unfortunately no inconsiderable number, who from a false modesty have objected to an examination, have been taken at their word, and treated for supposed hæmorrhoids, when in reality they had nothing of the kind, but were suffering from ulceration, polypus, or even cancer. The following are the chief questions which, before making an examination, the patients may be asked with advantage:

1. How frequently do you go to the closet?
2. Do you pass any discharge from the bowel, and what does it look like?
3. Do you have any pain, and does it come on immediately after passing a motion?
4. Does any part of the body come down at stool?
5. Do you pass any blood?
6. Is the pan ever sprinkled or splashed with blood as if it had come out in a fine jet?

The foregoing questions have the following significance: If patients say they have frequent calls to the closet extending over some months you will almost certainly find (if the trouble originates in the rectum) there is either ulceration, cancer, or stricture. On the other hand, if they complain of constipation or do not go to the closet more than once a day you may be pretty sure that none of these diseases are present. It is a common error for students to consider constipation as a symptom of stricture. In reality it is just the reverse, and patients with stricture nearly always complain of diarrhoea. If a discharge is complained of it is necessary to ask whether this comes from the interior of the bowel on going to the closet or whether it comes from the outside, as evidenced by stains on the linen. If from the inside and clear, like the white of an egg, it may be mucus from internal prolapse or piles. If the quantity is considerable, a villous growth or polypus may be suspected. If the discharge from the bowel is purulent or has a coffee-ground appearance there is possibly internal ulceration, fibrous stricture, or cancer. Discharge originating external to the bowel and staining the linen generally comes from fistula. When part of the body comes down at stool it will be either prolapse, internal piles, or polypus. Bleeding is common to almost all forms of rectal disorder, but there is one particular form of bleeding which is almost characteristic. If the pan is sprinkled with blood, whatever else may be the matter with the patient, internal piles are almost certainly present.

PAIN.

Any disease situated about the anus or the last inch of the rectum gives rise to pain, whereas extensive ulceration or cancer situated above the internal sphincter may be almost painless. There is a particular form of pain, however, which is of peculiar interest as regards the subject we are discussing, and when present is most suggestive. Let us consider the answer which the first of the two patients gave to this question. The pain was what brought him to the hospital. He says that for some months every time on passing a motion

he has severe pain, sometimes this starts whilst he is actually passing a motion, though more commonly it does not come on for half a minute or so afterwards. At times he describes it as positive agony, making him break out into sweat, sometimes it only lasts a minute or two, at others it may be half an hour or more before it goes; when it is gone he feels fairly comfortable till the next motion, when the whole phenomenon is repeated. A motion is so dreaded from the pain it causes that he often abstains from passing motions for days together.

The second case was a woman. Her general description of her symptoms was very much the same as in the first case, though in a less degree. The pain was described as of a burning nature, though occasionally pretty sharp, was often comparatively slight, and sometimes for a week or two she would have no pain at all.

From the description that these patients gave us of their condition it was almost certain that they were suffering from anal ulcer, and such after examination has proved to be the case. These ulcers may be situated in any part of the anal circumference, but in 9 cases out of 10 they are in the middle line behind. They are never very large, being seldom bigger than half the size of a threepenny piece, and are placed so that half their circumference is on the mucous membrane and half on the muco-cutaneous surface. They vary in depth, the recent ones extending only just through the superficial membrane. In the older ones the submucous tissue is destroyed, so that the fibres of the external sphincter muscle are visible at the base of the ulcer. Sometimes on examination in place of an ulcer a little hole may be seen, and on passing a probe into this it will be found that the muco-cutaneous surface is detached over a little space, the ulcer being covered in as it were by the surface tissue. These cases are of the utmost importance, for the little orifice leading to the submucous ulcer is readily overlooked, and I have seen many cases where, on account of this, the patient has been told that there is nothing wrong with the part. The way to examine a patient with symptoms of fissure is to get them to the edge of a couch in a good light, and then, telling the patient to strain down, the anal folds should be gently drawn apart with the fingers. The lesion then can be clearly seen; generally, just external to the site of the ulcer, will be found a little rose-coloured oedematous fold of skin. On no account should the finger be passed at the time of the mere examination. The sphincter spasmodically contracts, and exquisite pain is caused. If there is any suspicion of disease higher up the bowel, it should be examined under an anæsthetic at the time of operating on the fissure.

If a patient has the characteristic pain caused by anal ulcer, and yet nothing can be seen at an ordinary examination, the patient should not be pronounced free from disease till a second complete examination under ether has been made.

TREATMENT.

This may be considered as palliative and operative.

Palliative.—If the case has been of comparatively recent origin, if muscular fibres are not exposed, and there is no undermined muco-cutaneous surface or sinus present, there is a fair chance of a cure being effected by simple remedies. The motions must be kept soft by a laxative; a teaspoonful of the confection of senna early every morning is effective. Capsules of 15 to 30 drops of the fluid extract of cascara sagrada may be taken at bedtime, or the following dinner pill: Pil. col. co., gr. x; pil. rhei. co., gr. xx; mix, and divide into six pills, one to be taken at dinner time. The anus should be gently washed with soap and water night and morning, and on no account should paper be used in the closet, the part being cleaned with a sponge or cotton wool and water. Two ointments may be prescribed; the one a soothing ointment to be applied five minutes before the motion is passed, the other an astringent ointment to be used at night. It is better for the patient to apply this with his finger than by any form of ointment introducer, for the ulcer is just at the orifice, and if the patient strains down it can be effectually applied. Six grains of morphine to an ounce of unguentum petrolii is a good soothing ointment; for an astringent ointment subacetate of iron, 10 grains to an ounce may be used, or tannic acid in the proportion of 30 grains to the ounce. Another ointment I have seen occasion-

ally effectual is 15 drops of carbolic acid, 10 grains of powdered camphor to the ounce of simple ointment or unguentum petrolii.

Operative.—Palliative treatment may have failed, or the case from the first may be one better treated by operation. If the ulcer is of old standing and the muscular fibres exposed, or if the edges be undermined or a sinus present, palliative treatment is mere waste of time, for by an operation properly performed the patient may be cured. It should be done as follows: At bedtime two days preceding that of operation the patient should take two pills (pil. col. co. gr. iv, pil. rhel. 10 gr. vi, mix and divide into two pills); this will ensure the bowels being well opened the day before the operation. On the morning of the operation, and an hour before its performance, the bowels should be washed out by an injection of a pint of hot water. The patient being under ether in the lithotomy position, the sphincter is gently dilated. The ulcer is now thoroughly examined with a fine probe to see if any fistulous tract exists, and the extent to which the edges may be undermined. If a sinus exists it must be laid open; if there is no sinus, or if present after it has been divided, a speculum is introduced into the rectum. The surface of the ulcer is then divided in the middle by a clean cut. The incision should commence on the mucous membrane half an inch above the ulcer, and end on the skin half an inch or a little more below it. The depth should be such as partly to divide the external sphincter, and to accomplish this it would have to be at least a third of an inch in depth in the middle. It is quite true that in many cases a more superficial incision will suffice, but as superficial incisions are often insufficient, it is better to make a bolder one at once. Moreover, the depth of the wound makes little difference in the time taken in its healing. After the incision has been made, a narrow strip should be cut with a pair of scissors off the two edges, which will otherwise overlap and interfere with the healing. A strip of lint smeared with eucalyptus ointment laid in the cut, and covered with a pad of aseptic cotton wool, completes the operation. For a fortnight the patient should be kept in the recumbent position, and as in all other rectal operations, the wound should be thoroughly washed and redressed night and morning. A dose of castor oil is given to open the bowels on the fifth day, and after this a mild laxative every alternate evening. When the patient is allowed to get up, it will do him no harm to walk about a bit, but he should sit as little as possible till the wound is completely healed. Nothing retards the healing of a rectal wound so much as the congestion produced by long sitting.

Gentlemen, no doubt you will think that the operation and subsequent treatment is rather elaborate for so small a lesion as an anal ulcer. It is quite true that many of these cases are cured by caustics, slight scarification of the surface, or simple dilatation; but if you wish to do the best for the patient and yourself by making a certainty of the cure, let me advise you to try no half measures, but perform a carefully-planned operation, as otherwise you will certainly from time to time have a percentage of failures.

CELIOTOMY FOR VOLVULUS OF THE SIGMOID IN A MAN AGED 85: INTESTINAL DRAINAGE: RECOVERY.

J. GREIG SMITH,

M.B., M.A.,

Professor of Surgery, University College, Bristol; Surgeon to the Bristol Royal Infirmary.

BY

and CHAS. E. S. FLEMMING,

M.R.C.S.,

Freshford, Bath.

This case seems worthy of a short notice from the great age of the patient. In recording the case the opportunity is taken of giving a short description of the method of intestinal drainage which is believed to be most suitable in such cases.

The patient was under the care of Mr. Charles E. S. Fleming, of Freshford, Somerset; operation was performed on January 30th, 1895. There had been complete obstruction for a week. The symptoms were of the usual

character, and need not be detailed. The abdomen was distended to its utmost capacity, the parietes being hard and drum-like. There was a small umbilical hernia, which was very tender but not tense. The diagnosis was made of volvulus of the sigmoid flexure of the colon, but the presence of the umbilical hernia was recognised as a possible *vera causa*, and the parietal incision was made to enter the umbilical opening and to extend for 2 inches below it. Anaesthesia with the patient's stomach full of fluid was not free from risk, but Mr. Terry, of Bath, skillfully succeeded in establishing and keeping up without mishap complete unconsciousness with chloroform.

The umbilical hernia was only omental, and was easily detached. The fingers easily reached the sigmoid, which was enormously distended, and seemed to fill the whole pelvis and much of the lower abdomen. A fold was pinched up, pulled through the wound, and incised, when enormous quantities of gas escaped. The whole of the involved gut, as soon as it was small enough, was delivered through the wound, when the twist was at once manifest. There was one complete twist, perhaps a little more; the gut was only slightly inflamed at the seat of twisting, completely collapsed, and almost cord-like below, and ballooned up to great size immediately above it. The untwisted gut was further emptied, and replaced in the abdomen. As the abdomen was still greatly distended, it was decided to fix and drain the bowel for a few days.

The arrangements for drainage were made as follows. A piece of rubber tubing, about two feet long, and of the calibre of a crowquill was introduced, stretched over the point of a probe, through the small opening already made in the gut; this it fitted tightly, putting it on the stretch. Then a safety pin was made to transfix the peritoneal and muscular coats of the bowel by the side of the tube, and to pass through the side of the rubber tubing. This pin served to keep the tubing and gut attached, and, when the dressing was arranged, to prevent indrawing or extrusion of the gut. The peritoneum was not drawn forwards. Sutures were placed closely above and below the drainage opening, which were not to be tied till the gut was returned inside. Rolls of boris lint were placed around the gut under the pin, and one roll above it (Fig. 1). Over all was placed a broad strip of strapping carried round the back and split in front so as to interdigitate. This strapping effectually keeps the parts at rest, and prevents any chance of extrusion of the bowels (Fig. 2). The free end of the tubing was placed in a bottle which lay by the side of the patient.

Fig. 1.—Diagram to show method of draining the intestine. B, bowel; M, mesentery; T, rubber tubing; P, peritoneum pulled outwards. 1, Strapping; 2, pin holding tube. On the right (x) an enlarged drawing shows the details of fixation. 3, Dressing.

In this case it was necessary to provide only for the escape of gas and liquid feces, so the tube was small. If a larger tube has to be used, it is possible to fix it in the bowel by the help of a suture so placed that when the pin is removed the mere tying of this suture serves to close the opening in the bowel. Such suture should never be made to grip the walls of the gut bodily, otherwise sloughing may take place. The dressing presses the bowel against the rubber tubing; there is no risk of extravasation of the feces if this is properly attended to. In the diagram the peritoneum is shown as brought up to the opening in the gut; this is advisable in most cases to avoid the firm adhesion, preventing easy replacement, which takes place when bowel is laid on the raw surface. In this case the great age of the patient made strong adhesion improbable, and the parietes were thin, so the peritoneum was not brought up with the bowel.

Fig. 2.—Diagram to show arrangement for intestinal drainage.

The patient was fed by nutrient and stimulating enemata, and was soon able to take a little nourishment by the mouth. Flatus passed in quantities through the tube; the tube occasionally became blocked, but either pinching it or passing a small soft catheter down it into the bowel always cleared it.

On the third day the abdomen was nearly flat, and the patient was so well that Mr. Flemming removed the tube, the dressings being then removed for the first time. The wound in the bowel was closed by a Dupuytren's suture, the bowel was invaginated, and the parietal wound brought together over it.

Flatus was passed by the rectum on the same night, but there were two slight attacks of pain in the abdomen. Next day flatus did not pass by the rectum till the rectal tube was inserted and worn, when it passed freely. On the following day (February 5th) a turpentine enema resulted in the passing of liquid feces and great quantities of flatus. On February 6th castor oil produced two copious evacuations in two hours. The condition of the patient was now excellent.

On the night of the 8th, however, the patient had an attack of pain, with collapse, which suggested an attempt at the formation of another volvulus. Opium, strychnine, and belladonna were administered; and after two somewhat anxious days he recovered, and at once picked up.

On the 12th, compound liquorice powder, followed by a turpentine enema, produced a free evacuation. On the 19th he sat up in his chair. He had some swelling of the left foot and leg which retarded his recovery. A week later, he was out in the garden.

The latest note is on May 15th, which states that the patient has quite regained his strength, and is in fact better than before the operation, for he has quite lost his old attacks of pain in the abdomen; and, with the help of a cathartic pill, has a daily evacuation of the bowels. The swelling in the left leg has not disappeared, and may be due to thrombosis in the left iliac vein, where it is crossed by the sigmoid mesocolon.

REMARKS BY MR. GEORGE SMITH.—Ten years have now elapsed since I began to advocate and to practise evacuation and drainage of the intestines in obstruction. My

experience, which now covers one hundred cases of operation for obstruction, goes steadily to raise my estimation of the proceeding; and it is gratifying to note that the same holds true with respect to other surgeons. Intestinal drainage as an accessory is scarcely inferior to removal of the cause of the obstruction in many cases as a means of getting the patient well. Properly managed it can scarcely do harm, and adds nothing to the operative risk, while its benefits in reduction of the mortality are very conspicuous.

In the process of drainage of the intestine after an operation for obstruction, one element of supreme importance is simplicity in method. It ought to be capable of rapid application by the surgeon, and of being easily managed by the usual attendant. For the drainage tube, at first I used rubber tubing; then I tried celluloid, and, in several shapes and forms, I used it chiefly for two years. I have also used vulcanite and have tried Paul's glass tubes. But I have finally abandoned all hard and unyielding material, and have returned to the use of the simple pliable rubber tube. Tubes of hard texture, which do not yield to the constantly contracting intestine, set up irritation and cause a secretion of mucus, which necessitates dressing and is difficult to collect. Ligation of the gut round the hard tube, as in Paul's method, causes sloughing of a ring of bowel; I have tried it once, and, although the patient did well, was not satisfied with it. Perfectly satisfactory drainage up to the full size of the bowel, as for colostomy, can be carried out by rubber tubing without any outward secretion of mucus, and without any necrosis of intestinal wall.

The rubber tube has incidental advantages. If it becomes blocked it can easily be cleared by pinching—"milking" its contents onwards. It permits movement to the patient without any addition of risk. It can be introduced on the stretch, of a smaller calibre than the opening in the bowel, and, when resilient, it distends and accurately fits the intestinal opening. It can be fixed in the bowel with great ease and rapidity, a simple transfixing pin or ligature holding bowel tissue to tube wall. The whole process can be carried out in less time than it takes to describe it.

The tubing in every case should have stout walls; it must be capable of being bent well beyond the right angle without kinking. Its calibre varies according to the nature of the material it has to drain. For gas a tube of very small calibre suffices; for fluids in the small intestine a tube the size of a crow-quill suffices. In these cases the fluids are probably poisonous to the system, and they are secreted abundantly after the obstruction is relieved, therefore I think they should be quickly drained. For drainage of the large bowel, even if the feces are liquid, a larger tube may be used, because drainage is not so easy and also because rapid evacuation is very important. In all such cases of temporary drainage the tubing is fixed as described. In a young patient with a thick parietes I believe that replacement of the everted bowel is facilitated by bringing out the parietal peritoneum and fixing it to the bowel at the opening which holds the tube. In old patients with thin parietes this does not matter. It is possible to fix the tube in position by a suture so placed round the pin that merely tying this suture closes the opening in the bowel when the rubber tube is removed. A suture placed in the parietes in the line of drainage may be left untied till the drainage tube is removed; the opening is closed over the returned gut simply by tying the suture.

A similar proceeding with a larger tube converts drainage into the formation of an artificial anus. For this purpose I think Reclus's method of using a skewer to traverse the mesentery and support the extruded loop of bowel the best and simplest. A loop of colon pulled through the wound is supported on a skewer (I now use one of the vulcanite stirring rods used by chemists), the gut is opened by a cut with scissors and a large rubber tube is inserted, stretched over the skewer. It is fixed to the margin of the incision in the bowel either by a running suture or by a couple of safety pins. It is dressed as shown in Fig. 3. As permanent fixation is desired the peritoneum is ligured. Colostomy may thus be performed under five minutes, and it need never require two stages. The subsequent perfection or imperfection of the artificial anus depends on the judicious arrangement of

muscular fibres and fascia around the gut, and on other considerations which pass beyond the limits of this paper.

Fig. 3.—Diagram to show method of performing colostomy. B, bowel above spur; B', bowel collapsed below spur; T, rubber tubing; Sp., spur. At the top of the spur the black circle represents section of a supporting stiff rod.

As regards the age of the patient, special remark is scarcely called for, for it is now well recognised that mere age is no barrier to surgical operation. I have successfully amputated for gangrene the great toe of a gentleman, in his 98th year. I have made a complete excision of the mamma for cancer in a lady, aged 69, who is still alive and well in her 91st year. I have performed at least ten ovariectomies in patients between 70 and 80. If the patient is well guarded against shock and the operation is quickly performed recovery is quite as satisfactory in the aged as in the young.

A MODIFICATION OF THE OPERATION OF PYLOROPLASTY,

WITH A REPORT OF TWO CASES.

By A. W. MAYO ROBSON, F.R.C.S.,

Vice-President of the Surgical Section of the British Medical Association; Senior Surgeon to the General Infirmary at Leeds; Professor of Surgery in the Yorkshire College of the Victoria University.

THE principle of obtaining increased calibre in a strictured channel by dividing the narrow passage longitudinally and suturing the wound transversely, is as ingenious as it is efficient, and in no situation can such a procedure be of more service than in simple stricture of the pylorus, where the operation is known as pyloroplasty.

The invention belongs to Heineke, who performed his first operation in March, 1886, though the name of Mikulicz, who did the second in January, 1887, is sometimes attached to the procedure.

Simple stricture of the pylorus is far from common, and therefore the experience of any one surgeon must be somewhat limited: this must be my excuse for basing my conclusions on so small a number as two cases.¹

I think there can be no doubt that pyloroplasty will completely replace Loreta's operation, since with no greater or perhaps even less immediate risk, it affords a more certain prospect of freedom from relapse.

In writing this paper I have had an equally successful third case. Following the operation, the patient gained 2 stones in weight within formed on obstruction.

The modification of the operation by the use of the bone bobbin which I have adopted, not only expedites the procedure, but in my opinion renders it safer than when simple suture is employed. The following diagrams show better than words the original and the modified operations:

Fig. 1. First stage.

Fig. 2.—Second stage.

Fig. 3.—Third stage of the original method.

Fig. 4.—Third stage of the modified method as employed in the cases related.

It will be seen that by the use of a decalcified bone bobbin only two continuous sutures are required, the first to unite the mucous margins, the second the serous. The bone tube further secures an immediately and thoroughly patent channel, and affords protection to the line of sutures for from twenty-four to forty-eight hours, when union should be well established. The account of the following cases proves that the operation is both feasible in execution and satisfactory in results.

CASE I.—M. F., aged 34, residing in Scarborough, was sent to me by his medical attendant, and admitted to the Leeds

General Infirmary, January 10th, 1895. He gave the history of having been well up to five years before, when he began to have pain after food and vomiting, but he did not remember having vomited blood. His symptoms continued off and on until June, 1894, when he ceased work and sought advice. Between Christmas, 1893, and January, 1895, his weight diminished from 9 st. 5 lbs. to 7 st. 5 lbs.

On admission he was much emaciated, and the signs of dilated stomach were well marked. After taking food he had no rest until vomiting occurred; the vomit was sour smelling and yeasty but never contained bile or blood. He suffered much, not only from painful cramps in the extremities, which required morphine for their relief, but also from distressing spasms of the stomach, which could be distinctly felt contracting, the outline of the dilated organ showing through the abdominal walls. At times a sausage-shaped hard swelling could be felt a little above and to the right of the umbilicus; but as this was only occasionally felt, it was manifestly a contracting pylorus and not a permanent tumour. The stomach was washed out daily and the patient fed with peptonized food, but as all food produced pain and was rejected, rectal feeding was adopted. January 24th. Pyloroplasty was performed through an incision 3 inches long in the linea alba above the umbilicus. The pylorus was found to be surrounded by adhesions and tucked up to the under surface of the liver; its outer surface was puckered as if an ulcer had approached the peritoneal coat and had then healed without perforation. On opening the stomach close to the pylorus it was found that the pyloric orifice was contracted to the size of a No. 6 catheter, and that it was surrounded by cicatricial tissue. No shock followed the operation, and the after-progress was all that could be desired. Feeding by the mouth was begun on January 26th and the rectal feeding discontinued on January 29th. After the sickness due to the anæsthetic had passed off there was no further vomiting. The sutures were removed on the seventh day, when the wound was found to be healed. He rapidly gained flesh, and was discharged well and strong on March 2nd, having gained nearly a stone in weight, and being able to take ordinary food in full quantity.

CASE II.—W. F., aged 52, sent to me by Dr. Cheeswright, of Rotherham, on account of vomiting and loss of flesh, was admitted to the Leeds General Infirmary in the first week of April, 1895. He gave the history of indigestion for two years, but of being otherwise fairly well up to Christmas, 1894, when he began to have pain about two hours after food, which was at times followed by vomiting. The vomiting recurred every other day, when a large quantity of mucus and partly-digested food would be rejected. The vomit at first contained dark blood, though during the month before admission no blood had been noticed. During the early part of his illness there was marked tenderness over the epigastrium, but before admission the tenderness disappeared. He was not weighed until five weeks before admission, but in that short time he had lost a stone and a-half in weight.

On admission he had a starved look, and was feeble generally. The signs of dilated stomach were well marked, but no distinct tumour could be felt in the region of the pylorus. There were no other signs of disease. The stomach was washed out daily with a solution of boracic acid, and on April 8th pyloroplasty was performed through an incision 3 inches long in the middle line above the umbilicus. On exposure, the pylorus was found to be much thickened and surrounded by adhesions, which fixed it firmly to the under surface of the liver. After detaching adhesions it could be brought down sufficiently far to be manipulated. On making the longitudinal incision through the pylorus the channel was found to be surrounded by cicatricial material, leaving a passage which would only admit a No. 10 catheter. The operation, with the use of the bone hook, was performed as shown in the diagrams. The after-progress was perfectly satisfactory, and he began to take food by the mouth on the second day. In the second week he was taking solid food freely, and before going home at the month end he was eating large meals of the ordinary hospital diet. He never vomited after the operation, and the wound healed by first intention. When he left for home he had gained half a stone in weight and looked well.

With a little manipulative dexterity, the operation of

pyloroplasty can be done so quickly and with so little exposure of viscera that post-operative shock need hardly be feared, and as the incision through the pylorus is through cicatricial tissue there is little or no fear of hemorrhage; in fact, in the two cases related, not a single ligature was required. The only difficulty, and it is one which may usually be expected in these cases, is that the pylorus has to be separated from adhesions set up by the inflammatory process which has caused the stricture. These are better separated by the fingers than by a cutting instrument.

It will be found to facilitate the application of the sutures if the longitudinal incision through the pylorus is made rather nearer the lower margin, so that when the slit is sutured transversely the upper angle is well within view. As regards sutures, fine catgut is the best for uniting the mucous margins and fine silk for the serous surfaces.

For simple stricture of the intestine I have found the same operation to prove equally satisfactory.

HUNTERIAN LECTURES

ON THE

EXPERIENCE OF ST. GEORGE'S HOSPITAL IN LAPAROTOMY;

EXCLUSIVE OF GYNÆCOLOGICAL OPERATIONS,
FROM 1888 TO 1894 INCLUSIVE.

Delivered at St. George's Hospital Medical School

By T. HOLMES, F.R.C.S.,

Consulting Surgeon and Treasurer to the Hospital.

LECTURE III.—GASTROJEJUNOSTOMY: INTERNAL STRANGULATION AND STRICTURE OF BOWEL.

CONCLUSION.

THE operation of gastrojejunostomy appears to mark another real advance in surgery, attaining without inordinate risk in cases of pyloric obstruction the object which surgeons have long pursued, but with little success, by gastrotomy, in cases of œsophageal obstruction, namely, the prolongation of life in tolerable comfort and with the power of taking natural food. And I believe that this operation has been so successful that it has displaced or will displace the complicated and dangerous procedure of pylorotomy.

Our experience of gastrojejunostomy during the period covered by these notes has consisted of four cases, in three of which complete success was obtained. The fatal case was that of a woman, under Mr. Haward's care, advanced in life (aged 75) and suffering from cancer in the groin as well as in the stomach. She died on the fifth day after the operation. The necropsy furnished this interesting specimen, which shows the small but adequate artificial communication provided by the operation and also the total disappearance of the Senn's bone plates used to approximate the viscera.

In the successful cases one of the most satisfactory features was the rapidity with which the patient recovered appetite, strength, and flesh. Thus in a case under Mr. Bennett's care, in 1891, published in *The Lancet*, xxiv., 247, the patient had been suffering from nearly or quite complete obstruction of the pylorus and was in the last stage of emaciation. The operation was performed on February 27th, and he was discharged on April 23rd. During these two months he had increased $2\frac{1}{2}$ stone in weight. I may notice here that his weakness was so extreme that it was necessary to feed him by the mouth even on the evening of the operation, when egg and brandy was given, and he was ordered small doses of brandy and milk at frequent intervals during the night. This man died in the country about nine months after the operation from secondary deposit of cancer in the lung.

Another of the patients, also under Mr. Bennett's care, is since dead, having survived the operation nearly more than eight months. The case was not an encouraging one, for the malignant mass was not confined to the stomach, as I did not originate there, but spread from the umbilicus, where there was a mass of hard cancer, which passed towards,

TABLE I.—*Laparotomy for Intussusception—All Fatal.*

Name.	Age.	Date.	Surgeon.	Remarks.
1. W. B.	3 m.	Sept., 1890	Mr. Bennett	The intussusception could not be disengaged. An artificial anus formed.
E. B.	10 m.	Mar., 1891	Mr. Pick	Intussusception easily reduced, but recurred in two days. Again reduced, but the child sank.
2. F. I.	3 m.	Apr., 1891	Mr. Dent	The gut burst in the attempt to disengage the intussusception.
4. L. M.	4 m.	Apr., 1892	"	Barker's operation for resection of intussuscepted bowel. Sank immediately.
5. K. H.		Apr., 1893	--	The intussusception was not found till after death, which followed 3 hours after laparotomy.

TABLE II.—*Laparotomy for Kink and Volvulus.*

Name.	Age.	Date.	Nature of Case.	Surgeon.	Result.	Remarks.
1. J. W.	24	July, 1893	Kink probably from loaded bowel	Mr. Rouse	R.	Recovery delayed by suppurative parotitis.
2. Y. M.	20	Jan., 1890	Volvulus	Mr. Turner	D.	There was also a large intussusception, caused by an intestinal polypus. This was disengaged, but she never rallied from operation.
3. H. F.	58	Apr., 1890	Volvulus	Mr. Bennett	D.	Cause of obstruction not made out at operation. There was a volvulus near the commencement of the ileum.
4. J. B.	79	Aug., 1894	Volvulus	Mr. Dent	D.	The operation was abandoned; the colon being found to be in a gangrenous condition. There was a volvulus of the sigmoid flexure. Operation immediately on admission, but too late.

TABLE III.—*Laparotomy for Strangulation by Bands.*

Name.	Age.	Date.	Nature of Case.	Duration.	Surgeon.	Result.	Remarks.
				Days.			
1. R. P.	47	Dec., 1888	Band formed by a Meckel's diverticulum	5	Mr. Dent	D.	No action of bowels after operation; bowel above constriction in an incipient state of gangrene; operation 3 days after admission (3 days of constipation).
2. W. D.	27	Feb., 1889	Band	3	Mr. Pick	D.	Gut gave way at operation.
3. F. M.	31	May, 1889	Band formed by mesentery and diverticulum	7	Mr. Turner	D.	Gut ulcerated by band; vermiform appendix also perforated; case too complicated for successful treatment.
4. E. G.	—	Sept., 1889	Band	6	Mr. Dent	D.	Gut gave way and an artificial anus formed; gut above the constriction was gangrenous; operation too late.
5. L. G.	65	Feb., 1892	Band	8	Mr. Pick	D.	Gut gave way and was resected; very collapsed at time of operation; operation too late.
6. J. W.	30	Mar., 1893	Meckel's diverticulum	3	Mr. Dent	D.	Operation not performed till the day after admission; gut leaking, was resected; operation too late.
7. E. H.	49	Feb., 1894	Band	3	Mr. Sheld	D.	A band found and divided; gut ulcerated by it; incised, emptied, and sewn up; survived 4 days, but no action of bowels; another band was found <i>post moriem</i> , not tightly constricting the gut; operation on day after admission, fourth day of constipation.
8. J. P.	13	Sept., 1891	Meckel's diverticulum and another band	3	Mr. Pick	R.	—
9. J. T.	28	Feb., 1893	Two or three bands	3	Mr. Haward	R.	—
10. E. J.	37	July, 1893	Long band	2	Mr. Dent	R.	Peritoneal cavity drained for the first 24 hours after operation.
11. E. S.	45	Feb., 1894	Band	3	Mr. Haward	R.	—

TABLE IV.—*Laparotomy for Stricture of Bowel—All Fatal.*

Name.	Age.	Date.	Nature of Case.	Surgeon.	Remarks.
1. A. L.	69	Nov., 1891	Old polypus, nearly closing the small intestine	Mr. Haward	Inguinal colotomy was attempted, but the colon was flaccid; so the small intestine was drawn up, and an artificial anus formed.
2. J. L.	42	Feb., 1891	Schirrus of jejunum	—	The operation was more exploratory than effective. He died more than a month afterwards of pneumonia.
3. G. J.	40	June, 1891	Malignant stricture of colon	Mr. Dent	An artificial anus was formed. Death soon after operation.
4. G. L.	63	June, 1893	Malignant stricture of rectum	Mr. Pick	The seat of stricture was not discovered. An artificial anus was formed.
5. W. H.	—	Mar., 1894	Malignant stricture of sigmoid flexure	Mr. Dent	A band was found constricting the cæcum, and divided; but it was recognised that this had not produced total obstruction. He died in a few hours.
6. W. S.	39	Mar., 1894	Stricture, probably malignant, of sigmoid flexure	Mr. Haward	The bowel was opened above the constriction, and fixed to the abdominal wall.
7. E. H.	17	April, 1894	?	—	This youth died a few hours after operation. There was no <i>post-moriem</i> examination, and the notes are mislaid. It is believed to have been a case of stricture of the bowel.

lapping round the pylorus, and causing obstruction. The operation therefore was performed merely with the hope of prolonging life, and rendering it more tolerable. In this it succeeded completely. He returned here to die in February of this year. I produce the preparation from this case also.

The other patient was also operated on by Mr. Bennett. He was lately in the hospital, having then enjoyed twenty months of tolerable health and active life. When the operation was performed, he was so reduced that he seemed almost moribund. His weight increased after the operation from 8 st. 11 lbs. to 10 st. 2 lbs.

LAPAROTOMY FOR OBSTRUCTION.

We now come to the extensive and difficult class of cases in which laparotomy is performed for the relief of obstruction, the exact cause of which can in most cases only be conjectured. The success of the operation depends in a great measure on the anatomical cause of the obstruction, and in a great measure also on the promptitude of the operative interference. In my younger days, though the possibility of recovery was admitted and the operation was occasionally practised, nay, though possibly a few successful operations had actually been performed, it was looked on as a desperate measure, and was therefore almost always delayed too long; so that all the operations which I have myself practised, or which my colleagues performed during the period of my service here, were I believe unsuccessful. Now, however, we have a very different tale to tell; and though in some of the classes of obstruction we can still report no success, in others the percentage of recovery has been so encouraging as to inspire the surgeon with fresh hope, and to give fresh motives to both physician and surgeon for a more extensive and more careful study of the symptoms.

Cases of internal obstruction may be divided into (1) from the pressure of tumours; (2) from intussusception; (3) from volvulus or kink; (4) from bands crossing the intestine; (5) from stricture; (6) from hernia not perceptible externally; (7) from the lodgment of foreign bodies; of which last there are no examples in this list.

1. Total obstruction from the pressure of a tumour is of rare occurrence, but a case was spoken of in a former lecture in which an enlarged mesenteric gland so pressed on the bowel as to stop its action. Abscesses and hydatids often cause more or less obstruction, but this is seldom total. Gall stones, again, may produce obstruction, directly by impaction in the gut, or indirectly by exciting volvulus, but no such case is included in our list. I must refer you on this head to Mr. Mayo Robson's interesting paper lately read at the Royal Medical and Chirurgical Society, and to the discussion which followed.

2. The operative treatment of intussusception has not, in our experience, been successful. Most of the cases which I have found occurred in very early life. The infants were all admitted when in an advanced condition of the disease, and, as the operation was in all cases performed at once, the surgeon had not to reproach himself with any delay. Table I contains the leading particulars of these cases.

There was also another case, classed with those of volvulus, in which there was an intussusception produced by an intestinal polypus.

3. Our cases of laparotomy for kink and volvulus are shown in Table II.

4. *Intestinal Strangulation by Bands.*—The next class of cases of obstruction consists of those in which the bowel is strangulated by one or more bands crossing or encircling it, such bands being formed by a Meckel's diverticulum, by a peritoneal adhesion or adhesions, by a string of adherent and condensed omentum, or by some other structure of limited extent, such as an appendix epiploica adherent to a neighbouring appendix or coil of intestine. We have had numerous instances of this form of obstruction, and I think everything tends to show that if the case be dealt with sufficiently early, a good result may be fairly anticipated from surgical interference. On the other hand these bands are often very tense, and cut into the substance of the bowel rapidly; and if the bowel is incurably damaged, its resection introduces a formidable complication into the case, while frequently the patient's condition is not such as to permit so prolonged an operation, and then an artificial anus must be formed. But the more one sees of cases of laparotomy, the more strong I think will become the conviction of the undesirability of an artificial anus. It seems far better, if there is any chance of the patient's survival, to resect even a considerable portion of intestine and mesentery. Mr. Harrison Tripps has, however, recorded a most interesting case in which, after the formation of an artificial anus, a permanent cure was effected by the resection of a foot of intestine. The patient, he informs me, is now in perfect health a year after the operation.

We may then sum up our past experience of laparotomy for this form of obstruction thus. There have been 11 cases, of which 7 proved fatal. In 4 of these fatal cases the operation was evidently too late, the period of strangulation being five, seven, six, and eight days respectively; and the need for the promptest possible operation in such cases is shown by the fact that in the 3 other cases in which the period of strangulation was only three days, in each the gut had been fatally injured, so that it gave way. In one of these cases the lesion proved at once fatal, in the others an attempt was unsuccessfully made to remedy it—in the one case by the resection of the injured bowel, in the other by incision of the gut and evacuation of its contents, followed by suture. In the four successful cases, the period of strangulation did not exceed three days. (See Table III.)

I cannot do better than direct your attention to a most interesting paper by Mr. Dent,² founded in part upon some of these cases. Mr. Dent dwells with just emphasis on the need for an accurate study of the symptoms, which are usually sufficient to establish a pretty confident provisional diagnosis, and on the absolutely imperative duty of the surgeon in all such cases to lose no time in operating. He gives, also, a graphic picture of the processes by which the rapid disintegration of the bowel is effected, and lays down most valuable rules for the operation and after-treatment.

5. *Obstruction from Stricture.*—Laparotomy for stricture of the bowel is a far less promising proceeding, for the stricture is often malignant, and frequently also the diseased portion is so extensive as to preclude all idea of its removal, and then the only thing that can be done is to form an artificial anus or to implant the bowel above the stricture into a lower coil of intestine. Very commonly also in hospital practice the symptoms have been too indefinite to induce the patient's medical attendant to send him in until the condition is too far advanced to have much chance for success from any surgical proceeding.

The number of cases operated on was only 7, but they all proved fatal. In one case, however, the operation seems to have had nothing to do with the death, which occurred more than a month afterwards from pneumonia. (See Table IV.)

6. *Strangulation of an internal hernia*, that is, a hernia not perceptible by external examination, bears the strongest analogy to strangulation by a band. We have 4 cases on our record, only one of which was successfully dealt with. This was the case of a man under Mr. Sheild's care last September, in whom the bowel was strangulated in a hole in the mesentery. In this case there was also an inguinal hernia, but it was rightly believed not to be strangulated, so that no time was lost in exploring it. Two of the other cases were small Litre's hernia, strangulated in or near the abdominal ring; the strangulation was relieved, but the patient was seen too late for the operation to be effectual. In the fourth case the notes are not sufficiently precise to enable me to give you exact particulars.

The only case I have found of resection of the intestine for gangrene after hernia was a desperate one, and terminated fatally, as was inevitable. The woman, aged 58, had had a femoral hernia, which seemed to be perfectly reducible on her admission, though there was a history of strangulation for several days, and of repeated and violent pain. As stercoraceous vomiting came on the day after admission, it was decided to explore the abdomen in case the hernia had been reduced en masse. The cecum was found gangrenous and was resected, but the patient was in too weak a condition to rally from the operation, and died next day.

I have so far fulfilled the task which I set before myself, and have given you as complete a statement as I can of the experience of St. George's Hospital in this important department of medicine and surgery. But I must ask your patience for a few minutes while I venture on some observations on the general question of laparotomy, as seen in the light of this experience.

In the first place, it is obvious that there are many conditions, necessarily fatal if left alone, which are susceptible of cure by operation. Those which this series encompasses are intraperitoneal rupture of the bladder or intestine, freely perforating ulcer of the stomach or duodenum, internal strangulation, and internal hernia. These conditions admit

¹ BRITISH MEDICAL JOURNAL, 2 AUGUST 17th, 1894.

² BRITISH MEDICAL JOURNAL, January 26th, 1894.

of relief only by operation, and though internal strangulation may be palliated by enterostomy, none of them can be cured except by laparotomy. I think, then, that the opinion of the surgical world will be unanimous in saying that such cases should be treated in that manner; and, if so, it follows as a matter of course that the operation should be performed at the earliest moment possible, since peritonitis comes on with extreme rapidity, and very soon the condition will be hopeless.

Again, there are other conditions which perhaps can hardly be said to be necessarily fatal, but which are so dangerous to life that they may be practically regarded as incurable without operation. This may be said of acute diffused peritonitis from perforation of the appendix, and of subphrenic cavity from gastric or duodenal perforation. Here, again, it seems to me hardly to admit of argument that laparotomy is urgently indicated; and we have had ample evidence that the fatal results of delay are only a little less rapid in this than in the former class.

Another category may be formed of cases which admit, indeed, of cure by laparotomy, but not without great risk, and which are not necessarily fatal, at any rate for the moment. I speak of idiopathic and tuberculous peritonitis, of intussusception, of obstruction from kink or volvulus and of internal stricture. The nearer these latter approach to total stoppage or strangulation the more urgent is the indication to operate; but surgical opinion, and perhaps medical opinion to a still greater extent, is as yet divided as to the propriety of early interference in such cases, though it is impossible to doubt that if relief is not obtained by medical and mechanical treatment the delay will seriously prejudice the chance of success by laparotomy.

Next we have cases of hydatid cysts, of pancreatic cyst, of other non-cancerous tumours, and of limited abscesses in the abdominal cavity. The danger that such tumours will make their way into the general cavity of the peritoneum is very great, the patient's prospect of recovery is very much diminished if diffuse peritonitis has been thus set up, and the treatment by laparotomy is so very successful if undertaken before this has occurred, that I cannot myself doubt that early operation is a duty.

In cases of cancerous tumour or stricture it is doubtful whether the total excision of the tumour or of the viscera affected is worth its risks; but it is often possible to maintain nutrition and so preserve life by some "short circuiting" operation, of which gastro-jejunostomy is the most familiar example.

Finally, there are the cases of cholecystotomy and other operations on the gall bladder, operations performed on the ordinary surgical indications, for relief of pain and deliverance from future danger; and, as it seems, with no more than the usual risk and no less than the usual guarantee against recurrence.

If, however, it is so important in many cases to save hours, even minutes, of delay, are our hospital arrangements the best calculated to secure this end? Some surgeons have suggested that in cases requiring laparotomy "consultants should pass a self-denying ordinance, and leave the operation in the hands of the general practitioner." I cannot too strongly dissent from this suggestion. Delay involves great dangers, doubtless; but these operations are among the most difficult in surgery, and require, as Senn¹ has most truly said, that he who undertakes them should be "no tiro in surgery;" and the diagnosis requires also "no tiro in physic." That an operation can be better decided on and better performed at the hospital than at the patient's house, seems to me undeniable; and we may hope that as the fatal effects of loss of time become better understood the patients may be sent in earlier. Excluding traumatic cases, they should, I think, be still, as before, physicians' patients, but the house-physician might be instructed to send for both physician and surgeon immediately on the patient's admission, so that the consultation could be held without any further loss of time, and the operation performed, if necessary, on the spot.

If I were still in the active pursuit of operative surgery, and had thus taken a part in the noble surgical exploits about which I have been speaking, I should have become familiar with the details on which the success of these opera-

tions so much depends, and which have been so greatly modified of late, and so much improved. But alas! my most recent experience of laparotomy is nearly eight years old, and the whole proceeding has been revolutionised in that time. I cannot therefore speak with any authority on that subject; nor is it necessary. Treating of laparotomy for diffuse septic peritonitis, Mr. Lockwood in the current volume of the *Med. Mag. and Chir. Trans.* has given what seem to me admirable directions for the details of such cases. He has treated of the methods of stimulating the patient and combating the collapse before operation by subcutaneous injections and by alcoholic enemata, of the application of local warmth during the operation, of the kind of anæsthetic to use, of the necessity in some cases for evacuating the contents of the distended and semi-paralysed bowel by incision, and suturing the intestine (of which I have given you two instances from Mr. Shield's practice), of the great assistance which is often found in these operations from a stout suture passed through the abdominal parietes on each side to hold the incision open, and avoid the embarrassment of retractors, a device for which we are indebted to Mr. Shield; to the order in which the search should be conducted through the intestinal contents in seeking for perforation or obstruction; to the method of protecting the intestines, which have to be withdrawn out of the abdominal cavity; to the method of washing out the peritoneum, and carefully separating the adherent intestines; to the union and drainage of the wound, the care of the patient during the operation, and his treatment and feeding afterwards. Certainly the perusal of Mr. Lockwood's paper will lead all readers to agree with Senn that these operations are not the part of a "tiro in surgery;" while both the necessities of the operation, and the requisites for after-treatment, require the best resources of a great establishment, where every means of treatment is ready, and there are plenty of skilled persons to apply them.

The only matter which did not come within the scope of Mr. Lockwood's paper, as far as I can see, is the method of intestinal resection and suture; but this I do not venture to treat of. Operating surgeons alone are competent to judge of the value of the various contrivances recently introduced for obtaining safety in removing portions of irretrievably damaged bowel, and speed combined with security of adaptation in the reunion of its divided parts; and the time has not yet been sufficient for any consensus of opinion on the subject.

NOTES ON THE LIMERICK FOOD POISONING CASES.

By SM CHARLES A. CAMERON, F.R.C.S.I.,

Professor of Chemistry and Hygiene, Royal College of Surgeons in Ireland; M.O.H. Dublin.

THE following brief account of this sad case may interest the readers of the *BRITISH MEDICAL JOURNAL*: On July 3rd, 1895, about 70 inmates of a convent and boarding school in Limerick became very ill after dinner, and for several days suffered from vomiting and purging of a severe character. Three ladies died, and many of the other inmates were for several days in a precarious condition. Poison being suspected, portions of the vomit and dejecta were sent to me for examination on July 5th; also a portion of cornflour which it was suspected might contain poison—but none was found in it, nor in the other matters sent to me. Suspecting the case to be one of ptomaine poisoning, I telegraphed for portions of everything the patients had for dinner; but the only items available were sugar and sodium bicarbonate, both of which were pure. It has been clearly ascertained that the poison was not in the meat used, for some persons who had partaken of it were not ill, and the history of the carcass that furnished it was made out and negatived the hypothesis of unsoundness or disease in it. It appears that a custard formed part of the dinner, and that all who partook of it sickened. The cook (one of the sufferers) states that she prepared the custard as follows:

Tuesday, July 2nd, I took 4 quarts of skimmed milk of previous night, boiled it, added about $\frac{1}{2}$ lb. loaf sugar, added 2 table-spoonsful of cornflour, and boiled again; this was done in a tin vessel. At 3 or 4 p.m. resumed making of custard: Beat up 8 or 10 eggs, all fresh except one,

¹ *Journal of Surgery*, p. 81, edition, 1893.

which had a reddish brown colour but no bad smell, poured them into the milk, which was then about the temperature of tea, and then poured it into an earthenware bowl; removed to a cold place during the night. On Wednesday, July 2nd, 9 A.M., the custard had become quite thin, of the consistency of cream. Poured it over 1 or 2 quarts of strawberries, about 1 quart of which had been gathered on the previous night. Whipped the whites of eggs used above with 1 lb. of sifted sugar and spread over strawberries and custard on glass dishes.

That the strawberries were the cause of the illness is negatived by the fact that three or four persons who used gooseberries and not strawberries with the custard were amongst the sufferers.

The inquiry is therefore narrowed to the question, Was the *materies morbi* in the milk or eggs? It would seem that some surprise was manifested by the custard remaining thin. When I first heard this fact I thought that the fluidity might be due to the liquefying influence which certain bacilli have on gelatine and albuminous matters, though the rapidity of their action in this particular case seemed surprising. I therefore had a custard made similarly to that described by the cook, and found that it remained as thin as rather thin cream. This want of consistency was, however, due to the albumin of the eggs not having been coagulated by heat, for when my custard was heated to near the boiling point (as should always be done) it became on cooling quite thick. That a highly poisonous substance (tyrotoxin) is generated in milk not necessarily very stale, is well known. In the Limerick case the milk was at least two days old when consumed, as at 11 o'clock on the previous day it was skim milk of "the previous night." It was however boiled, and, after the addition of cornflour and sugar, again boiled.

The question is, could the milk in presence of sugar and cornflour have generated tyrotoxin from the time it was boiled at 11 o'clock on Tuesday until it was produced at dinner at 1 o'clock on Wednesday. The time of year was favourable to the fermentation of the unstable mixture. Suspicion falls stronger on the eggs. I have learned that they were market eggs and had been purchased four or five days before they were used. Though not putrid they were more or less stale, and one had a curious colour, described by one person as resembling that of claret. Now, after the addition of the eggs to the luke-warm milk, sugar, and cornflour, there was no further heating, and it is clear that the egg albumen was not coagulated. There is reason to believe that the discoloured egg was cracked and, if so, micro-organisms had access to its interior. The viscera of two of the ladies who succumbed to the attack were examined for ordinary poisons with negative results, but a substance was extracted from them which gave all the characteristic reactions of ptomaines. The quantity available for examination was altogether insufficient to differentiate the ptomaine or ptomaines present from others, of which there seem to be a very large number. I am not aware that in any case of ptomaine poisoning the ptomaine was extracted from the viscera and identified.

Another patient died on July 16th, thirteen days after partaking of the custard. The inquest was held same day, and the verdict given was in accordance with my evidence.

In this case it is much to be regretted that neither the custard nor the matter ejected from the patients on the first or even second day of their illness was available for bacteriological and chemical examination.

A case of poisoning from stale eggs is recorded by Dr. Marshall in the *Gazette Médicale de Paris*, 1890.

OBSERVATIONS ON THE ACTION OF THE LEE METTFORD BULLET ON BONE AND SOFT TISSUES IN THE HUMAN BODY.

MADE DURING THE CHITRAL EXPEDITION.

By SURGEON-LIEUTENANT JAY GOULD,

Indian Medical Service; Staff-Surgeon, First Brigade, Chitral Relief Force.

AFTER the actions of Malakhand Pass, Khar, and Swat River, Major-General Alexander A. A. Kinloch, C.B., kindly allowed me to go into the surrounding villages, collect and treat Swatis wounded by the magazine rifle. After overcoming the suspicions of these tribesmen, I succeeded in

collecting some twenty-five or thirty cases, and herewith attach short notes of the most interesting of them:

CASE I.—A male, aged 26. The entrance wound was small, the edges cleanly cut and very slightly inverted. It was situated 2 inches below and behind the right great trochanter, and passed obliquely upwards and to the left through the osseum. The wound of exit, above and behind the left great trochanter, was very little larger than the wound of entrance; its edges slightly everted, but not lacerated. The osseum was simply drilled; the bones were neither fractured nor splintered, the muscles and other soft tissues were apparently little damaged. With free drainage and the usual antiseptic precautions the patient rapidly recovered, and in about three weeks was ready to fight again.

CASE II.—A male, aged 18. The entrance wound was behind the internal condyle of the right arm. It was small, the edges cleanly cut and slightly inverted. It passed obliquely downwards and outwards through the olecranon and the upper part of the shaft of the ulna. The exit wound was 2 inches below the tip of the olecranon and half an inch to the outer side of the posterior border of the ulna. The olecranon was pierced obliquely, no fracture could be made out, and only very slight splintering of the bone. The damage to the soft tissues was trifling. Rapid recovery took place, with good movement of the elbow.

CASE III.—A male, aged 27. The wound of entrance was in the middle third of the inner aspect of the right thigh. It was small, the edges cleanly cut, and there was little inversion. It passed obliquely downwards and outwards through the extensor muscles, grooving slightly the front of the shaft of the femur. The exit wound was at the outer aspect of the thigh in the upper part of the lower third. The bone was not fractured, but a small amount of bone was removed in very small pieces. The recovery of the patient was rapid.

CASE IV.—A Mullah, aged 45. The entrance wound, small and sharply cut, was situated in the left submaxillary region, about the level of the hyoid. It coursed upwards and to the right, through the lower border and horizontal ramus of the lower jaw of the right side. The wound of exit in the lower part of the cheek was a little bigger than that of entrance and slightly everted, but its edges were not lacerated. The bone was not fractured, but the lower border was splintered, though not to any great extent; some small fragments were removed. The teeth were intact. The injury to the soft tissues was slight.

CASE V.—A male, aged 18. The entrance wound was 2 inches above the external condyle of the left arm; the exit wound exactly opposite on the inner aspect of the arm. Both entrance and exit wounds were small, and there was no laceration of skin. The bone was drilled, but not fractured or splintered. Recovery was rapid, the wounds being perfectly healed in fifteen days.

CASE VI.—A male, aged 35. The entrance wound was behind the surgical neck of the humerus. It passed backwards and towards the vertebral column, passing the axillary border of the scapula, and coming out over the centre of the infraspinous fossa. The injury to the bone was slight. No splintering could be made out. The damage to the soft tissues was trifling. Recovery was rapid.

CASE VII.—A male, aged 30. The entrance wound in the upper third of the right forearm passed directly backwards through and to the outer side of the radius. The exit wound was opposite, on the posterior aspect of the forearm. Both entrance and exit wounds were small and sharply cut. The bone was not fractured, but slightly splintered, and several small pieces were removed. The damage to the soft tissues was slight. Recovery was rapid.

CASE VIII.—A male, aged 32. The entrance wound was at the anterior and inner aspect of the upper third of the right thigh; that of exit at the centre of the posterior aspect of the thigh 2 inches below the plicated fold. Both wounds were sharply cut. There was no laceration or comminution of the skin, and the damage to the soft tissues was slight. The bone was uninjured. Recovery was rapid.

CASE IX.—A male, aged 30. The entrance wound at the middle of the right forearm was small, the edges sharply cut, and slightly inverted. It passed directly backwards through the ulna. That of exit, on the posterior aspect of the fore-

arm was a little bigger. There was no laceration of its edges. The ulna was fractured, and slightly splintered. Some fragments of bone were removed. The damage to the soft tissues was slight. Recovery was slow, as the patient attended very irregularly, and allowed the wounds to get dirty.

CASE X.—A male, aged 17. The entrance wound was on the anterior aspect of the left forearm, in the lower fourth. It was small, and its edges sharply cut. It passed directly backwards through the lower extremity of the radius and out on the posterior aspect of the forearm above the wrist. The bone apparently was not fractured, but there was a slight amount of splintering, and a few small fragments were removed. The patient at the time of the report was making a good recovery; the movement of the wrist and fingers was fair, and improving daily.

CASE XI.—A male, aged 30. The entrance wound was at the anterior and posterior aspect of the middle third of the right thigh. That of exit was on the same level on the anterior aspect, the bullet passing outside the femur. The damage to the muscles, etc., was slight. Both entrance and exit wound were very small, and there was no laceration of the skin. Recovery was rapid.

CASE XII.—Male, 75. The wound of entrance was at the inner and posterior aspect of the lower third of the right leg. It passed behind the tibia, through the fibula, and the wound of exit was on the external aspect of the leg on a level with that of entrance. The entrance wound was small, with sharply-cut edges; the exit wound a little larger, with edges slightly everted. The fibula was fractured and splintered, but not severely; several small fragments were removed. Recovery was rapid.

CASE XIII.—A male, aged 30. The bullet had entered through the left cheek below the malar bone, and found exit in the right cheek at the anterior border of the masseter muscle, and at a slightly higher level than the entrance wound. Both wounds were small and sharply cut. Both superior maxillary bones had been pierced, together with the nasal septum. The palatal process of the superior maxillary bones was uninjured. The second bicuspid and first molar teeth on the left side were loosened, and were subsequently removed. No splintering or fracturing of either bone could be made out, and there was little or no subsequent swelling or inconvenience. Rapid recovery ensued.

CASE XIV.—Male, aged 26. The wound of entrance was at the posterior aspect of the left shoulder below the acromion process. That of exit at the anterior aspect of the arm about 2 inches below the shoulder joint. Both wounds were small. The edges of the exit wound were everted. The humerus was pierced below the head; a few small splinters were removed, but fracture could be made out. The soft tissues were apparently little damaged. Recovery was fairly rapid, with good movement of the arm.

CASE XV.—A male, aged 29. The entrance wound was over the left shin just below the patellar tubercle of the tibia. That of exit was at the back of the calf, 3 inches below the bend of the knee. Both wounds were small, and the edges sharply cut. The tibia was pierced, but not fractured, and there was a small amount of splintering. The soft tissues were apparently little damaged. During treatment there was a good deal of discharge. Two weeks after the wound was inflicted I enlarged the entrance wound, and removed two loose pieces of bone half and three-quarters of an inch long respectively. After this the discharge visibly diminished, and the patient made a rapid recovery.

CASE XVI.—A male, aged 17. The wound of entrance was at the outer side of the right arm, in the upper third. That of exit was at the posterior aspect of the arm, on the same level as that of entrance. Both wounds were very small. The edges were sharply cut, and there was no bruising or ecchymosis. The bone was untouched, and the damage to the soft tissues must have been very slight, as it healed up in a very short time. This man stated that he did not know he was hit, and that he had no pain at the time or afterwards.

CASE XVII.—A male, aged 40. The entrance wound was 3 inches above the ankle-joint, on the anterior aspect of the right leg; the exit wound was on the posterior aspect of the leg at the same level as that of entrance. Both wounds were small. The edges of the exit wound were everted. The tibia was pierced and splintered slightly, but there was no fracture

of the bone. The damage to the soft tissues was slight, and recovery was rapid.

CASE XVIII.—A male, aged 25. The entrance wound was on the outer side of the right thigh, about the middle, that of exit on the same level at the inner aspect of the thigh. The bullet had passed in front of the bone, not touching it. Both wounds were very small, and the whole damage very slight.

CASE XIX.—A male, aged 20. The entrance wound was at the anterior aspect of the left forearm, about 2 inches below the elbow-joint. The exit wound was on the posterior aspect at the same level. The bullet had passed outside the radius, but touched the bone, which on examination I found loose and rough. Two or three very small pieces were removed. The bone was not fractured. Only trifling damage had been done to the soft tissues, and recovery was rapid.

CASE XX.—A male aged 45. The entrance wound was just below the right malar bone, that of exit on the left side below the centre of the lower border of the zygomatic arch. The bullet had passed obliquely backwards from right to left. What course this bullet took I am not prepared to say. I could not pass a probe to any great length and found it utterly impossible to establish communication between entrance and exit. This patient had no severe symptoms, no pyrexia during treatment, and will soon be well and none the worse for being shot.

I have merely quoted in above cases the course of the bullet, giving in each case its effect on bones and soft tissues, purposely omitting details of treatment. Speaking generally my treatment of all cases of bullet wounds in the field is free drainage and surgical cleanliness, combined with as many antiseptic precautions as it is possible to apply in a field hospital on the move. The principal dressings used were iodoform in powder, boracic lint, and antiseptic absorbent wool.

There can be little doubt that from a humanitarian point of view the Lee-Metford rifle is a perfect weapon. The bullet obviously inflicts very little damage on the soft tissues and on bones its action is apparently not very severe, preferring rather to go through a bone than to badly fracture it. In one or two cases quoted the bone has been fractured, and in another case doubtful fracture. I am unable to state at what ranges these men were shot. Again I may have been unfortunate enough to treat only their slightly wounded cases, and the most unfortunate circumstance of all was my inability to get hold of any of their dead, open up the wounds and see what the actual effect of the bullet on bone is. These tribesmen almost invariably carry away their dead with them, and bury them rapidly.

From the little experience I have had in injury to bone tissue by the Lee-Metford bullet, I certainly think it causes but slight shock, and doubt its capacity of putting a man out of action. Instead of badly fracturing and comminuting the bone, it appears only to drill the bone and slightly splinter the edges. A hard bone like the shaft of femur it in all probability would fracture if it hit it fair, otherwise it would groove and glance off it. It apparently has little comminuting action even on the skull bones. How is it that this bullet does, or apparently does, so little harm? Is it that the small diameter, comparatively sharp apex and very hard thimble, combined with enormous spin and velocity, enable it to act as a rapidly working drill, and, consequently, simply bore a hole in the bone?

Very marked indeed is the action of the service bullet compared with Tweedie's, which is used for sporting purposes. In the latter the apex of the thimble is filed oil, and its destructive effect on bone is enormous. On several occasions after shooting black buck and chintara with a Lee-Metford sporting carbine, using Tweedie's bullet, I have dissected the wound, and found that the bones touched by the bullet were literally smashed in all directions.

On the strength of the few cases I have quoted and others still under observation I infer that the Lee-Metford rifle is an excellent weapon in every respect but one, that is, would it stop a rush?

S. J. AARONS, M.B., C.M., and W. MACRAE TAYLOR, M.B. and C.M., have been appointed resident surgeons to the Edinburgh Royal Maternity and Simpson Memorial Hospital, and enter on duty on August 1st.

GUNSHOT INJURIES PRODUCED BY THE LEE-METFORD RIFLE.

By H. KNAGGS, M.B., B.Ch.Dub.,
Surgeon-Captain Army Medical Staff.

LANCE-CORPORAL B. was admitted to hospital about midnight on April 1st, 1894, suffering from the effect of gunshot wound. On examination there was found a small circular wound, $\frac{1}{2}$ inch in diameter and somewhat depressed, at the left side, between the ninth and tenth ribs, at their junction with the cartilages. It was surrounded by a contused ring about $\frac{1}{2}$ inch deep, marking the wound of entrance. The wound of exit was situated on a level with the third lumbar vertebra, and 1 inch to the right of the spine; it was about the same diameter as the other wound, and presented three small triangular flaps which were everted; there was no confusion about it, and there was no external hæmorrhage.

The pulse was small and fast, and he was suffering from the general symptoms of shock. The abdomen was flat and resonant, even in the iliac fossa when the patient lay on his side, and the area of hepatic dulness was not diminished. He complained of great pain about the anal region, and it was discovered that complete paralysis of the left lower extremity existed. He was put under the influence of morphine, and rallied partially, the pulse becoming comparatively full and strong, but about 5 A.M. on April 2nd he became very restless, and gradually sank and died at 6.30 A.M.

The post mortem examination was made twelve hours after death by the coroner's surgeon. The following notes were made at the time: The body was well nourished, and *rigor mortis* marked. The external wounds have already been described. The abdomen was flat. A large quantity of dark blood escaped on opening, and occupied also the abdominal cavity. The areolar tissue beneath the skin in the vicinity of the wound of entrance was much ecchymosed and pulpy. The spleen had been torn by the passage of the bullet at the lower margin. The wound was stellate, 2 inches in transverse and 1 inch in vertical measurement. The spleen substance was exposed, and protruding from the capsule. The areolar tissue around the left kidney was infiltrated with blood. The kidney was uninjured. The jejunum was injured in two places about 6 inches apart, and close to the duodenum. Two elliptical pieces of bowel were destroyed, amounting to half the diameter of the gut. The edges of the wounds were contused, and blood was extravasated between the layers of the mesentery. The psoas muscle on the left side was perforated opposite the third lumbar vertebra; the opening in the muscle was about half an inch in diameter.

The bullet striking the lateral aspect of the body of the third lumbar vertebra, near its upper surface had destroyed

the lower angle of the cavity thus formed a fracture extended downwards and forwards to the inferior surface of the body, separating about one third of its area.

The pedicle on the left side was destroyed. The bullet, passing across the spinal canal with a slight inclination downwards, had severed the lath of nerves going to form the sacral plexus on the left side, and, splitting the right lamina

Fig. 2.—Inferior surface of vertebra, showing fracture through body and anterior aspect of laminae: the right lamina is completely divided, the split in the left is made evident by the insertion of a pin.

from its junction with the spine to the inferior articular process, emerged close to the spine.

The left lamina was also fractured on its anterior aspect, but the fracture passed behind the inferior articular process into the spine, and was incomplete, no bone being actually detached.

REMARKS.—The rifle was discharged at a distance of about 10 yards, and the cartridge was loaded with black powder. The course of the bullet was inwards, backwards, and downwards. From recent experience one would expect that the discharge of a small bore projectile with high velocity and at such close proximity would produce effects much more severe and with greater comminution of hard parts than was found in this case. The wound in the spleen, though of small extent, was distinctly "explosive" in character, but the injury to the bone was limited and well defined. Though a considerable portion of the body of the vertebra was destroyed, the wound of exit was hardly larger than the wound of entrance, which is unusual in such cases, especially at short ranges, where the exit of a bullet is often marked by a wound of great extent. The case goes to demonstrate the fact pointed out lately by Professor Horsley, in a lecture given before the Royal Institution, that the destructive effects of bullets with high velocity vary directly as the viscosity of the body.

DISLOCATION OF CARPUS BACKWARDS.

By THOMAS H. MORTON, M.D. ARMD.,
Sheffield.

The infrequency of dislocations at the wrist-joint justify recording any case coming under a surgeon's notice. Accidents which might produce a luxation of the carpus generally cause fracture of the radius either in the middle or lower third, or near the joint (Colles's), or a separation of the epiphysis. Persons when falling with outstretched arm, the palm striking the ground, receive the shock mostly on the end of radius. The radio-ulnar and other ligaments unite with tense tendons to protect the joint, securing the carpus *in situ*. The following case may throw a little light upon the position when falling which influenced dislocation.

J. A., aged 16, on April 25th, 1893, when playing during breakfast time in the yard of a steel works, running and kicking, fell between two rails, his left arm backwards, the hand

Fig. 1.—Showing injury to the postero-lateral aspect of body and dislocation of vertebra in left position.

an irregular wedge-shaped piece of bone about half an inch in length, immediately below the intervertebral disc. From

probably slightly pronated and under him. The thumb hit the ground, as a contused abrasion over metacarpal showed. The arm at first glance had the appearance of Colles's fracture.

On examination the radial and ulnar processes were in the normal plane. The carpus projected upwards and backwards but not to any great extent, as is shown by the photograph. Reduction could be effected easily by fixing the forearm, grasping the hand and making forcible extension. A slight grating was felt. That no radial fracture existed was proved by the natural position being sustained when the patient moved the joint, and also by the satisfactory rotation of the radius without crepitus or displacement. The arm was put up in back and front splints, bandages, and a sling until May 4th, when a short gutta-percha splint was secured on the palmar aspect of the joint. There was some swelling about the wrist, but good movement. On May 13th a simple bandage applied.

Although the position of limbs in persons falling cannot always be exactly ascertained, it may be assumed that in this case the injured arm was not placed anywhere voluntarily, and that the principal weight borne by the thumb side of the hand conducted to jerking the carpus backward, perhaps irrespective of any muscular action which so often influences fractures and dislocations.

MEMORANDA:

MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, Etc.

A CURIOUS FRACTURE OF THE FOREARM.

THE accompanying sketch will serve to illustrate a somewhat unusual fracture of both bones of the forearm in a boy who lately came under my treatment in Mandalay.

Moung Po Nee, a well-nourished, healthy-looking Burman boy, aged 12 years, was brought to the hospital on March 14th, 1895, with his left forearm in the condition shown in the

sketch. Both bones of the left forearm were incompletely fractured or bent at the junction of the lower and middle third, so that the lower third formed an obtuse angle with the rest of the forearm. On comparing the two sides no dissimilarity could be detected in measurements, neither was there any deformity other than that caused by the bending of the two bones. The history was as follows. While at play the patient fell. He put forward his left hand to break the fall, and a fellow playmate fell across the back of the forearm. The result was that the arm gave way, and assumed the position seen in the diagram.

The patient was anaesthetised, and the injured arm was slowly bent into its normal position without difficulty. In doing this a soft crepitus was felt. The arm was put up in splints in the ordinary way. On April 12th the splints were removed, and a week later the boy left the hospital well.

Is it not remarkable for a fracture of this nature (incomplete) to occur in a healthy child aged 12 years?

W. G. FRIDMORE,

2nd Burmah Battalion, Mandalay.

Surgeon-Captain, I.M.S.

A CASE OF TETANUS NEONATORUM.

On January 1st, 1895, I was called to see an infant on account of some difficulty it experienced in sucking. The infant was 10 days old; it seemed perfectly healthy; was full grown and plump, presenting no congenital peculiarities. The mother, who had been attended in her confinement by a midwife, stated that for the two previous days the child had been unable to suck; she noticed that it did not yawn or gape, and that there was resistance to moving the jaws. On examination it was at once evident that there was hardening of the masseters on both sides; the lower jaw was quite fixed, the moderate force used not overcoming the spasm. All the other joints were quite normal, the muscular system was natural, and the knee-jerks were present. The umbilical stump was normal; it showed no signs of suppurative; it had received the familiar treatment, and had been dressed with fuller's earth powder.

With some difficulty the child could be fed with a spoon, and was thus able to swallow a little milk. It did not seem to be in pain. Pulse and temperature were normal. On January 3rd the jaws were immovably fixed; it was absolutely unable to suck, and could hardly get any nourishment with the spoon. Convulsions now appeared on the left side of the body; in the intervals of the clonic spasms the joints were becoming gradually rigid. On January 7th the infant was in a pitiable condition; no food had been taken at all for several days. The jaws were firmly clenched; there was occasional foaming at the mouth, and all the joints were perfectly rigid; the vertebral column also being stiff. The convulsive seizures were frequent. The left lower limb was in a state of adduction and inward rotation and quite immovable. Death appeared so imminent at any moment that all active measures for the sustenance of life were suspended. On January 10th, that is, on the twelfth day of the disease, when the infant was twenty days old, it was horribly emaciated, pinched and wrinkled, the tonic spasms were more intense, the hands and feet were crossed and rigid, the spine was unyielding. Not a particle of nourishment had been taken for a whole week. Death occurred three days later at noon of January 13th.

REMARKS.—The frequency of this disease among the newborn is subject to considerable variation, ranging from severe epidemics to sporadic cases of extreme rarity. A severe epidemic occurred early in the century in the island of Heimacy, off the coast of Iceland; it has occurred epidemically also in Ireland; but the home of tetanus neonatorum is undoubtedly in the warm climates, especially in the West Indies and the equatorial regions of South America. The causes assigned to the disease, such as uncleanness, impure air, exposure to cold and wet, are merely predisposing. The one etiological factor is the bacillus tetani, which gains an entrance through the umbilical cord. An unhealthy condition of the cord has often been noticed in these cases; it may be in a state of inflammation, suppurative, or even gangrene, and it has also been observed that greater cleanliness exercised in dressing the cord has been followed by a diminution of the disease.

The suggestion may occur that in the case recorded above

no infection was introduced by the use of the fuller's earth powder in which some spores of the bacillus may have existed. The case is, however, noteworthy for the duration of the disease, extending over fifteen days, the infant having eaten for ten days without any nourishment whatever. Usually death occurs in from one to five days. Except in this respect the case was fairly typical of what is happily now an exceedingly rare disorder.

J. SNOWMAN, M.R.C.S. Eng., L.R.C.P. Lond.

Black Lane, E.

HEMORRHAGE AFTER TOOTH EXTRACTION.

Remembered like briefly to make known a simple method of stopping continued bleeding after extraction of teeth, which has proved quite effectual in my hands in several cases, in place of which plugging, various styptics, the actual cautery, &c., had been tried without success. It consists in passing a double silk thread through both sides of the torn gum, either with an ordinary curved needle or a handled needle, and then tying firmly over the alveolar border. In none of the cases in which this method has been employed has it failed to stop the bleeding immediately and permanently. The stitch may be removed at the end of forty-eight hours. The merely temporary success or complete failure of the usual methods, and the perfect success of that described, led me to think it may prove generally serviceable in what is frequently a very troublesome, if not dangerous, form of hemorrhage.

JAMES McNAUGHT, M.D., M.R.C.S.

Waterfoot, near Manchester.

LABOUR IMPEDED BY COILING OF THE FUNIS.

On attending Mrs. B. for her eighth confinement, I found her head well down and presenting, with the face looking to the front. As she had a similar presentation and a comparatively easy labour last time, I expected a speedy and natural termination. The pains were strong and regular, but the head made no progress. After waiting some time, I delivered with the forceps, and in the following disposition of the head found the cause of delay. It passed up over the left side of the chest, round the neck, down across the breast to the outside of the left ankle, which it completely encircled, and then to the right ankle around which it coiled in the same way. The feet were drawn closely together, and the head lay up over the front of the body. The funis was 25 inches long, and about half of it was coiled round the child.

Harwick.

NEWTON COTTAGE HOSPITAL AND DISPENSARY.

ALL STONE IMPACTED IN THE CYSTIC DUCT REMOVED BY INCISION: RECOVERY.

[By W. G. SCOTT, M.R.C.S. (Ed.), Senior Surgeon to the Hospital.]

F., aged 29, a married woman with three children, had suffered for five years from attacks of violent pain in the right hypochondrium, radiating over the abdomen and to the right angle of the right scapula. This was accompanied by sickness and slight jaundice. In the intervals there was no pain in the right hypochondrium and tenderness, and motions normal in consistence and colour.

She was a thin anæmic woman, and presented a slight protrusion of the conjunctivæ. The abdomen was flattened, the right hypochondrium and lumbar regions a hard, tender, sausage-shaped tumour, which gave the impression of being packed with gall stones, extended to the umbilicus. It could be moved a little to the left of the umbilicus, and pressed into the right loin. It moved freely with respiration, and appeared to come from under the surface of the

liver. The kidney could not be felt, and the urine contained no albumen.

Operation.—An incision 3½ inches long was made to the left of the linea semilunaris. The gall bladder presented; it was the size of a tennis ball and very tense. Five ounces of a glairy fluid, like the white of an egg, were removed by aspiration. The gall bladder was drawn into the wound and opened. The walls were found to be markedly cedematous. One stone, the size of a sparrow's egg, crenated on the surface and creamy-white in colour, broke on manipulation, and the remaining fragments were removed by syringing and a scoop. On passing the finger to the under surface of the liver a stone, slightly larger in size, could be felt firmly impacted in the lumen of the cystic duct. I was unable to reach it by probing through the duct. An attempt was made to crush it with padded forceps, but firm pressure made not the slightest impression. It was impossible to manipulate it into the gall bladder. The liver was therefore slightly tilted up and an incision large enough to allow the removal of the stone was made over its site. The mucous and fibrous coats were closed with interrupted silk sutures, and the peritoneal with Lambert's sutures. The abdomen was washed out and the gall bladder stitched to the edges of the wound with silk sutures. The rest of the abdominal wound was closed and a drainage tube was left in the gall bladder. The second stone was hard, crenated on the surface, and resembled the other in shape and colour.

For ten days after operation the dressings were practically dry, and three weeks elapsed before any bile appeared through the wound. The quantity then was slight and it ceased in a few days. The bowels were opened on the fifth day and the motion was natural in colour. The patient developed delusions (there was a family history of insanity). The wound was dressed and strapped over and she was allowed to get up, and finally left the hospital on March 21st with bile-stained discharge from the sinus.

On May 2nd an attempt was made to close the sinus; the mucous surface was pared and closed with silver sutures. This failed. Since the operation she has much improved in condition, has had no return of her original pain, and is able to do housework (she had been practically useless for the previous two years). Her mental condition is much better. The sinus is still discharging but the amount is much less and the opening appears to be slowly closing.

REMARKS.—The comparatively long continued suppression of discharge, which I take to be due to inflammatory thickening causing temporary closure of the lumen of the duct, the result of the incision, the easy solution of the difficulty by this method of procedure are points of interest in this case.

REPORTS OF SOCIETIES.

EDINBURGH OBSTETRICAL SOCIETY.

Wednesday, July 12th, 1894.

A. H. FREELAND BARBOUR, M.D., President, in the Chair.

THE CONDITION OF MIDWIVES IN SCOTLAND: SHOULD MIDWIVES BE REGISTERED IN SCOTLAND?

The discussion was opened by Dr. BENNY HART, of Edinburgh, who referred to the various attempts to register midwives, and to the fact that Lord Balfour's Bill only applied to England, but would probably later be extended to Scotland. He complained that the discussion thus far had been conducted with too much feeling. He was glad the Bill was in the hands of Lord Balfour of Burleigh, and the selection of Sir William Turner as the Chairman of the General Medical Council's Committee was an excellent one, and such an one to inspire the confidence of the profession. He referred to the fact that some 80,000 or 90,000 births occurred in this country yearly, that more than half of these were attended by midwives, and that the great majority of these so-called midwives were quite untrained. Apparently there were some 10,000 to 15,000 such women in England and Wales. He then went rapidly over the clauses of the Bill lately before the Legislature, and pointed out its defects. The whole question, he admitted, was one of great difficulty. No State House was now required. In any scheme of registration existing right

would have to be recognised. There were certain definite objections: (1) It was admitted that 500,000 births were attended yearly by more or less untrained and ignorant midwives, yet it was proposed to register these merely on application; (2) registration was not education; (3) there was no provision in the Bill made for education; and (4) no scheme of thorough education was possible in this country at present. He suggested that we might have registered midwifery nurses, which the public would more readily understand. He maintained that no midwife was competent to attend labour on her own responsibility. Why, then, should a physician not first see the case, and, if quite normal, hand it over to a nurse? Briefly put, the whole matter seemed to resolve itself into these questions: 1. What preliminary education was to be insisted on? 2. Were there facilities for hospital training? 3. What demand was there for midwifery nurses? 4. What evidence was there of malpractice? Dr. Barry Hart's position briefly was that, keeping in mind the unlikelihood of an effective training for some time, we were face to face with the danger of launching a large number of unqualified women on the public. Might we not, then, have less severely trained nurses to not under qualified medical supervision?

Dr. BAKER (Dundee) spoke strongly in favour of the registration of midwives, and referred to his experience in practice amongst the poor of Dundee. Many of these people were too poor to pay a medical practitioner. A great many foolish objections had been urged against registration, amongst others that a new order of practitioners would thus be created; but all this existed even now, and there was no control over the existing order of affairs save in cases of malpractice. As things existed at present, a midwife might undertake and treat the puerperal state. Now, were she registered, she could be restrained from such treatment. What, then, were we to do? He believed that poverty was the key to the position. Were we, first, to leave things as at present, and allow midwives to certify stillborn children, etc.? Or secondly, were we to make use of the Poor-law medical officers? Thus, he thought, could not be attained for a long time. Thirdly, should there be insurance against confinements? Or fourthly, should there be cheaper medical work? The alternative to the registration of midwives was the registration of midwifery nurses, but this only meant protection to the rich.

Dr. CONNELL (Peebles) said he preferred the registration of midwifery nurses rather than midwives, though he felt the difficulties. Thirty years ago a sensible neighbour was usually called in, but in his district the doctor was now almost always sent for. This, he believed, was because knowledge had permeated into the minds of the public. If midwives were to be registered, why not also bonesetters? It was right to improve nurses, but he thought that the responsibility must still be left with qualified medical practitioners. Then what was a natural labour? This was really the crux of the whole matter in relation to the registration of midwives. He confessed he failed to see the difficulty of providing payment to a practitioner. People had seven or more months' notice, and they ought to make provision to meet this. To register midwives as they now existed was to go back to the Middle Ages.

Dr. McVIE (Chirnside, Berwickshire) said practically he had not heard of a midwife in his district. No one employed her if a doctor could be had. The feeling among the working class in Berwickshire was that they ought to lay aside money for the confinement as much as for the rent. Because a patient could not pay a guinea, was that a reason why a poor woman should not have the benefit of skilled assistance? Why should not women doctors take up some of this kind of work? In some quarters the question appeared to be one of cost, but he did not think improvidence should be encouraged or made easy.

Dr. BALLANTINE (Dalkeith) was for leaving things pretty much as they were. If there was registration at all it ought to be limited to fully qualified women, and how in the existing state of affairs were these to be got?

Dr. LUCAS (Dalkeith) said his experience had been among midwives who had been trained in Edinburgh, and he found that after a little experience they did very well, and that in several cases of difficulty they had acted in such a way as to cause no reflection. The position of a country doctor with-

out the help of a nurse would be absolutely intolerable. It had been said that the whole question was a commercial one, but that was a difficulty which had never occurred to him.

Professor SIMMONS (Edinburgh) thought that the constitution of a special group of women with a certain inferior status was an experiment of a very dangerous kind. Midwifery could only be met by thoroughly trained practitioners. The women at present engaged in midwifery did very well so far, and he did not know that registration would greatly add to their worth. It would certainly give much more work to the General Medical Council. He supposed that by and by medical provision would have to be made for the poor.

Sir WILLIAM TURNER said that this Bill as amended on report was a very different Bill from that lately considered by the General Medical Council. He had not seen it until he entered the room. He had now glanced rapidly over it, and he found it so much altered that he could scarcely recognise it again. For example, the definition of a midwife had entirely dropped out. This definition was a limitation: it referred to women who undertook to attend cases of natural labour without the supervision of a medical practitioner. The Bill as amended on report apparently admitted midwives to attend all cases. He objected to the term midwifery nurse. A midwifery nurse should be on the same level as a surgical nurse, that is to say, solely to act under the supervision of a medical practitioner. Now, it was proposed to give women under the term midwifery nurse an initiative, and not to confine them to act as a midwifery nurse or as a surgical nurse. Then what was to be done with the existing midwives? To put them on the Register right away was felt to be a very sweeping proposition. The General Medical Council knew too well the difficulties ahead, from their experience of the *Dentists' Register*. The various suggestions of the Council's Committee had been almost entirely ignored. He noticed that there was a change in the constitution of the Midwives Board. In the draft it was proposed that this should consist of 12 persons, now it was 45, and one of them a woman. What was the Incorporated Midwives' Institute? It consisted of a body of philanthropic ladies who had applied to the Board of Trade for a charter of incorporation. Excellent ladies, no doubt, but what particular claim had they to play this particular part? He was unable to give any information. The three new members were to be appointed by the Lord President, and they also would probably be philanthropic. In all they would have six philanthropic persons. The midwife in Scotland seemed to him to be an accident, if he judged rightly what had fallen from many speakers today; but she was a clamant necessity in England, and there was in England a great amount of malpractice. If so, then these women ought to be educated and fitted for the work they had to do. He felt that he must support any properly constituted scheme for the education of midwives, but one of the great blots in this Bill was the neglect of the means of education. This practical matter must be met. There was no need to examine unless they were first educated. The General Medical Council would see to it that these women shall be properly educated, as tested by a rigid examination. It seemed to him that some of the speakers had failed to remember that education preceded examination and registration. In this amended Bill the difficulties were made still worse, because it was no longer a normal labour but a knowledge sufficient to attend any labour which was required.

Dr. BARRY TURNER said that he could add little to what had been so ably stated by Sir William Turner. He thought that in Scotland registration of midwives was not required. He knew of some practitioners who had several midwives under their supervision and found work to support them. In the Bill as amended on report a midwife was a full-fledged practitioner. The whole aspect of the matter was thus changed, and changed in a very serious way.

Dr. NORMAN WALKER said that he did not believe that any educated woman would ever submit to having a midwife to attend her. In his experience in country practice in the north of England he found few midwives. He had only met with one doctor in the same district who was in favour of the registration of midwives. Newcastle, he said, had solved the difficulty for itself by establishing a central bureau where doctors attended. He was sorry to say that there were still towns in England where medical men paid to women calling

themselves midwives a certain percentage on the cases sent to them.

Dr. THATCHER spoke as a teacher of nurses for twenty years. He said that women who had had a training and women who had not had been classed together. He took it that midwives were absolutely essential in some parts of Scotland; for example, in mining and colliery districts practitioners had not time to attend to all the cases. Properly qualified women were therefore an absolute necessity. As to training, he thought that a three months' course was too short. Women, so far as his course was concerned, had examinations theoretical and practical of no trifling kind. He expected such an amount of knowledge as would be equivalent to a pass-mark in the subject of midwifery for a medical student. He had had considerable experience of being sent for by trained women, and had never seen any bad result, nor had these women failed to detect the proper time at which to send for skilled help.

Dr. JAMES CARMICHAEL (Edinburgh) asked if Dr. Thatcher would have them understand that he expected or got from such women as he trained an amount of knowledge of midwifery sufficient to pass the final examination in medicine.

The PRESIDENT (Dr. Barbour) thanked the guests and especially Sir William Turner, Dr. Batty Tuke, and Dr. Norman Walker for contributing to the discussion. He thought the weak point of the amended Bill was the lack of definition of the term midwife, as Sir William Turner had rightly pointed out. Grave objection must also be made to the proposed constitution of the Midwives Board. Dr. Berry Hart was against the registration of midwives, but in favour of the registration of midwifery nurses. This made the further difficulty of the introduction of a new set of nurses. He thought the practical conclusion of the debate was that in Scotland at least there was no great need for the registration of midwives, or even of midwifery nurses. It was quite evident that there was no such call in Scotland as in England. One result of this discussion was that all would watch this Bill very carefully, and especially along three lines: 1. What is the definition of a midwife? 2. What provision is to be made for the education of midwives? 3. What is to be the composition of the Midwives Board?

DINNER.

At the close of the discussion, members and their friends dined together in the Waterloo Hotel, when Professor A. R. Simpson was the guest of the evening in respect that the twenty-fifth anniversary of his appointment to the Chair of Midwifery in the University of Edinburgh occurred near this date. The toast of "The Queen" was proposed by the PRESIDENT; that of "Our Guest" by Dr. JAMES RITCHIE; the "University of Edinburgh" by the PRESIDENT; and responded to by Sir WILLIAM TURNER; and "The President" by Dr. GEORGE THOMSON. Songs and stories added to the pleasure of the evening.

REVIEWS.

REGULATIONS AS TO DEFECTS OF VISION AND OTHER PHYSICAL DEFECTS WHICH DISQUALIFY CANDIDATES FOR ADMISSION INTO THE CIVIL OR MILITARY GOVERNMENT SERVICES. By S. O. MACNAMARA, F.R.C.S. London: J. and A. Churchill. (Pp. 31. 2s.)

ABOUT ten years ago Sir Joseph Fayrer, lately President of the Medical Board at the India Office, conceived the excellent idea of defining the standards of vision required for the various services, military and civil, under the administration of the Government of India. With the aid of Messrs. John Cooper, O. Macnamara, and H. Cayley rules were drawn up for this purpose, which obtained through Sir Joseph Fayrer's influence the sanction of the Secretary of State for India. These rules were subsequently published, together with some explanatory notes for public information, by Messrs. J. and A. Churchill, and two editions appeared in 1885 and 1887 with a preface by Sir Joseph Fayrer, whose name appeared on the title page. The pamphlet under notice appears to be in the

main a reproduction of Fayrer's pamphlet, but the preface is written by Mr. MACNAMARA, under whose name the publication is issued. The title is changed by the addition of the words "and other physical defects." This addition is explained by the first few pages, which consist of a reproduction of the regulations laying down the physical qualifications for officers of the army, and an extract from the Army Medical Regulations laying down a systematic drill for the examination of recruits. Regulations as to "physical defects which disqualify" for other public services are conspicuous by their absence. Some changes have been made in the descriptive matter referring to refractive defects and colour blindness, and the methods of detecting and measuring these.

This portion of the pamphlet is correct and concise as far as it goes, but as the general practitioner will probably refer doubtful cases, say of astigmatism and diplopia, to the expert, these dissertations on ocular defects and aberrations are not likely to prove practically useful to either class. The pamphlet is, therefore, incomplete in some respects and redundant in others; it is also misleading in one or two places. The visual requirements of the Royal Navy, for example, are stated to be, in short, perfect form and colour vision. This is true as regards sailors and engineers, but chaplains, doctors, and clerks are allowed a moderate degree of refractive error corrected by glasses. Again, the Civil Service Commissioners are said to "refer each case to a competent medical adviser, leaving him to apply whatever tests he may deem suitable, and whatever standard the particular situation may require." This is not quite the case, for the Commissioners indicate by means of their forms and regulations the conditions which are held to disqualify for the Civil Service, and the tests and standards applied to candidates are not so entirely left to the discretion of the examiners as is here stated. The pamphlet does not altogether fulfil the expectations raised by its title.

LE MUSÉE DE L'HÔPITAL SAINT LOUIS. Iconographie des Maladies Cutanées et Syphilitiques, avec Texte Explicatif par MM. ERNEST BENIER, A. FOURNIER, TENNESON, HALLOPRAD, DU CASTEL; avec le concours de M. HENRI FRULARD, Administrateur du Musée, Secrétaire-General, et M. L. JACQUET, Secrétaire de la Société de Dermatologie et de Syphiligraphie. [Coloured Representations of the Casts of Diseases of the Skin and Syphilis in the Museum of the Saint Louis Hospital in Paris, with explanatory text.] Paris: Rueff et Cie., Editeurs, 106, Boulevard Saint Germain. (Imp. 4to.)

THE richness of the celebrated museum of the Saint Louis Hospital has been rendered possible by the combination of the unrivalled artistic talents of M. Baretta, the abundant supply of clinical material, and the wise and enterprising patronage of the physicians to that famous institution. In their introduction the compilers of the atlas in which this collection is to be represented state with truth that M. Baretta—who is the possessor of a special paste—by his capacity in moulding and in colouring, has produced a series of models of skin diseases of unequalled perfection, which are admired by all medical men who have seen them.

The projected Atlas, of which the two first parts are before us, will reproduce in coloured plates the casts at present existing in the hospital museum, and the scope and method of the work will be best understood by a summary of their contents. The first plate represents a typical case of tuberculous lupus of the centre of the face, the cast being taken from a patient of M. Besnier, who signs the explanatory letterpress. First there is a careful detailed description of the various appearances as seen in the plate, then the peripheral part of the eruption is described, special attention is called to the shades of colour, the form of the isolated tubercles is pointed out, the smooth appearance of their surface, their size, their appearance when confluent. Then the colour, surface, and infiltration of the central part are described. Facing the coloured plate is a woodcut in which the outlines of the plate are given and in which all the points alluded to in the description are marked out by numbered lines. A description of the plate under the respective numbers is placed below it,

these are applicable to the corresponding parts of the coloured plate. The whole affords an object lesson to the student of equal interest and value. There then follows a description by M. Beaulieu of the history of the case and of the treatment which was employed.

The second part or number presents a coloured representation of the dermatitis herpetiformis of Dabring, with the accompanying outline chart which gives the references to the various appearances. The plate shows the hand, wrist, and part of the forearm of a patient of M. Tenneson, who gives an excellent description of the case and an analysis of the various lesions, with remarks on the diagnosis and differential diagnosis of the case. A detailed clinical history follows.

The Paris school has long held a foremost place for the excellence of coloured illustrations, but we have never seen anything finer from the hand of even a Parisian artist than these two plates. Their excellence and truth to Nature are remarkable. It is very rarely that it can be said of a plate that the diagnosis could be made from it as easily as from the living subject, but in these two instances this could be said with justice. A good test of the artistic excellence of an atlas of skin diseases is the success of the representation of vesicles, bullae, and pustules. Judged by this test, the plate of dermatitis herpetiformis may be pronounced as nearly perfect as can be.

The serious pretensions of the publishers that the practitioner who has to make a diagnosis in a case of skin disease would be able, if provided with this Atlas, to establish his diagnosis by comparing the appearances in his case with those of the plate which most resembled it, and that he would find in the accompanying text all the elements of rational treatment, is amply borne out by the numbers that have appeared. Armed with this work the practitioner living remote from the great centres will be able to reduce to a minimum the disadvantages of his position as regards an accurate knowledge of diseases of the skin.

An English translation of this work is in course of publication, under the title of *A Pictorial Atlas of Skin Diseases and Syphilitic Diseases*. The editor is Dr. J. J. Pringle. The English edition will be published in twelve parts, each containing four plates, with explanatory text, with the exception of the last part, which will contain five plates. The translation is well done, and the whole will form a veritable museum of skin diseases as far as pictures can replace the actual patients or specimens.

A JUNIOR COURSE OF PRACTICAL ZOOLOGY. By the late Professor MILNES MARSHALL and C. HERBERT HUNT, Ph.D. Fourth edition, revised by Dr. HUNT. London: Smith, Elder, and Co. 1895. (Cr. Svo, pp. 518, 73 illustrations. 10s. 6d.)

SINCE the issue of the third edition of this well-known textbook the sad death of Professor MILNES MARSHALL has left to Dr. HUNT the sole responsibility of the present issue. The changes effected by him are both more numerous and more extensive than those in the second or third edition, and are such that are calculated to render the volume more convenient in consequence. So far as concerns the arrangement, the chief changes are in the chapter on the dissection of the rabbit—the dissection of the head has been deferred to a late stage. Experience fully justifies the propriety of this change, as the author remarks, many students in dissecting the head render the subsequent dissection of the neck impossible. In the chapter on amphioxus many changes have been made, and these suffice to bring the account of the anatomy of this animal more into accordance with the results of recent work. Dr. Hunt has, however, only added a comparatively small portion of these results, observing that "it is difficult to determine how far one should go in recording in a practical laboratory guide for junior students, results which few junior students, if any, will be able to verify for themselves in the laboratory." This observation, which is taken from Dr. Hunt's preface, is one that will bear consideration of all lecturers and teachers, and its truth—certainly as regards junior students—will, we think, not be called in question. In a textbook of this nature, which has long achieved its success and is reckoned as the standard volume on the subject, criticism is out of place; we have

simply recorded the above changes as indicating the conscientious way in which Dr. Hunt has fulfilled his trust in giving us another edition of a textbook which is thus allowed to remain as a fitting memorial of the work of one of our best loved teachers.

NOTES ON BOOKS.

A Handbook of Pathological Anatomy, based upon the Catalogue of the Pathological Museum, University College, Liverpool. By RICHARD BOYCE, M.B., George Holt Professor of Pathology, and J. HILL ABRAHAM, M.D., M.R.C.P., Assistant to the Professor of Pathology. (Liverpool: Issued by authority of the Medical Faculty, 1895. Demy 8vo, pp. 510.)

The practice of issuing such volumes as this, which is now rapidly gaining ground in many of our medical schools, is one that cannot be too highly commended. Such volumes facilitate the study of pathology by correlating the symptoms of disease during life with the tissue changes found in the post-mortem room. In order to bring this about the pathological anatomy of each section of a system, such as "lips," "tongue," "oesophagus," "stomach," etc., in the case of the diseases of the alimentary tract, is generally discussed, and then illustrated by a series of specimens furnished with short clinical and descriptive notes. Surgical and medical pathology are in this way equally treated, as well as the special pathological anatomy relating to the female generative organs, skin, eye, ear, parasites, etc. In this way the authors have produced what is practically a very valuable catalogue. The advantages of such a handbook to students is obvious. The descriptions and general discussions are written in a style that is at once accurate and clear.

Surgical Pathology and Morbid Anatomy. By ANTHONY A. BOWLBY, F.R.C.S., Assistant Surgeon St. Bartholomew's Hospital. (London: J. and A. Churchill, 1895. Cr. 8vo, pp. 684. Illustrations 183. 10s. 6d.)—When a volume which is essentially a student's textbook has reached its third edition, this fact is ample evidence alone that the volume has fulfilled its main object. Mr. Bowlby is an actual teacher, and his works have all the more value from this fact. He writes in a clear and incisive style, and his descriptions are not overburdened with detail. The increasing importance of bacteriology has been recognised in the present edition by contributions from Dr. Kanthack, who has rewritten the chapter dealing with micro-organisms in their relation to pathological processes, and who has also added to various chapters such information in the various pathogenic bacteria as the scope of the work demands. Several chapters and paragraphs on fresh subjects which have of recent years become of increasing interest to surgeons have also been added. Twenty additional drawings have been inserted, and these are of the same excellence as those in former editions. Mr. Bowlby's manual is an excellent textbook and one well worthy the attention of students.

Die spezielle Chirurgie in fünfzig Vorlesungen: ein Kurzgefasstes Lehrbuch für Aerzte und Studierende [Special Surgery in Fifty Lectures: a Concise Textbook for the Use of Practitioners and Students.] Von Professor Dr. EDUARD LERCH, in Halle, Mitglied der Kaiserlichen Leopoldino-Carolinischen Deutschen Akademie der Naturforscher. Zweite wesentlich vermehrte und verbesserte Auflage. (Jena: Gustav Fischer, 1895. Imp. 8vo, pp. 1034; M 18.)—To readers of German who wish to keep themselves in touch with Continental surgery, this second and much improved edition of Professor LERCH's textbook will be found of service. It not only presents with more conciseness than is usually expected in German works a complete review of all branches of practical surgery, but it is also an excellent epitome of the teaching of the late Professor von Volkmann by a pupil and worthy successor. Although the first edition was published but five years ago, the rapid progress of modern surgery has compelled the author not only to enlarge his book, but also to rewrite many of the chapters. In his endeavour to render this a complete and useful book he has paid special attention to the sections on cerebral and abdominal surgery, and on tuberculous affections of the

bones and joints. We regret that we cannot congratulate the author on his illustrations, many of which are rough and wanting in clearness.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE
ALLIED SCIENCES.

LAWES'S DISINFECTANT FLUID.

Messrs. LAWES CHEMICAL COMPANY, LIMITED, have forwarded us for examination a sample of their disinfectant fluid. It is a brown liquid, with an empyreumatic odour, which has nothing disagreeable in it, and which greatly resembles the odour of good tar. When mixed with water it forms an emulsion of milky appearance and of slightly alkaline reaction. According to a testimonial given by Professor Henri Beye, it contains the superior homologues of phenol, insoluble in water and maintained in a state of solution by means of soda. For use the strength recommended is 1 part of the fluid to 100 of water. A solution of this strength we found would kill *Bacillus pyocyaneus* in five minutes—which was the least time tried—no growth occurring in broth after several days, while the control grew luxuriantly. This fluid is stated to be perfectly harmless, and, if further experiments confirm this statement, it ought to be a valuable addition to our list of antiseptics. As far as our experiments went, we consider it to be all the proprietors claim for it.

AN OPERATING AERO-URETHROSCOPE.

Mr. E. HENRY FENWICK, F.R.C.S. (Surgeon to the London Hospital) has had made for him an operating aéro-urethroscope. The first instrument was made for him by Leiter, of Vienna,

but Messrs. Down Brothers, of St. Thomas's Street, have made alterations and improvements. Mr. Fenwick points out that since the method of inflation has come into use the investigation of the penile urethra has become both rapid and accurate, but the difficulty which the new instrument is intended to obviate is that the glass diaphragm employed to prevent the escape of the inflated air necessarily prevents the introduction of any instrument. The advantage of treating the diseased surface when in the tense condition is obvious. Diseased and turgid folds become flat surfaces; crevices which may hide inflammations are rolled out; rings of stricture and membranous obstructions are put upon the stretch, and when in this condition fly on the slightest touch of the knife; swollen glands project from the surface and can be incised with certainty. Mr. Fenwick believes he has overcome the difficulty indicated by the use of double tubes.

The instrument consists of an ordinary urethral cannula, inside which is another movable tube—"the instrument carrier." The end of this inner tube is armed either with a knife (n) or curette (c) or brush. It can be projected from the cannula by pressing on the shield (m). Directly the pressure is taken off it springs back under cover through the action of a spring (s).

The instrument is not intended to replace the urethrotome, for it is useless in any stricture other than the large calibred or the membranous. Its main use is in the treatment of chronic gleet.

A THERMO-ANÆSTHETIC INHALER.

Dr. R. W. CARTER, of Weymouth, has designed a new form of ether inhaler, to which he proposes to apply the name thermo-ether inhaler. It is designed to maintain an equable temperature around the bottle containing the ether, or other anæsthetic fluid. The general form of the essential part of the apparatus is shown in the accompanying drawing. The anæsthetic bottle (A) is graduated to hold 3ij, and provided with a Buxton funnel (n) for filling. The connection for the face piece or tube for operations about the mouth is shown at x, while the connection shown at w leads to a small bellows

by compressing which, air is driven through the anæsthetic. The anæsthetic bottle is surrounded by a hot-water jacket (w), which is provided with a funnel (n) for filling and a venthole fitted with a plug (p) for use during filling. A stick of Japanese tinder is lighted and introduced in the cylinder (u) into the under chamber (a r). This chamber is provided with a venthole (v), and the rate at which air is admitted to the tinder, and therefore the rate of its combustion is regulated by a shutter (s). The apparatus is suspended in front of the anæsthetist by a strap, attached to the loops (L) which passes over his shoulder. The anæsthetic bottle is surrounded for about three-fourths of its circumference by the hot water jacket, the front being left open to allow the quantity of the anæsthetic to be

read. If there is only one case to be anæsthetised it will be sufficient to pour about two or three ounces of water at 100° F. into the jacket, but the temperature of the water may be regulated by opening or closing the shutter (s), which admits air to the smouldering tinder.

The advantages which Dr. Carter claims for this apparatus are, that it produces less, if any, asphyxia, that the anæsthetist has complete control over the anæsthetic, that as the ether is administered in the same way as chloroform in Krohne's improved Junker's inhaler the vapour is given only in inspiration, and the ether is not contaminated with the products of inspiration. For an operation lasting more than fifteen minutes a bag is necessary as in the ordinary ether apparatus; in some patients a bag may be required even for a short operation.

The apparatus is made by Messrs. Krohne and Esesman, 8, Duke Street, Manchester Square, W.

THE GRACE TESTIMONIAL.

At an examination for inspectors of nuisances, held by the Sanitary Institute at Huddersfield on July 12th and 13th, 1893, 16 candidates presented themselves and 12 passed.

WATERBORNE TYPHOID:

A HISTORIC SUMMARY OF LOCAL OUTBREAKS
IN GREAT BRITAIN AND IRELAND,
1858-1893.

A Report Prepared for the Parliamentary Bills Committee
of the British Medical Association.

By ERNEST HART, D.C.L.,
Chairman of the Committee.

(Continued from page 90.)

CHARACTERS OF TYPHOID FEVER.

The compilation of the tabular account of waterborne typhoid outbreaks has not been without its interest in regard to special features portrayed by the disease in its numerous methods of manifestation; and it may not prove altogether unwise to briefly chronicle some of the more special notes which I have made in passing. Thus, at Ing-ham, in 1869, Mr. Netten Radcliffe, in reporting on a limited outbreak of fever (No. 14), which was undoubtedly due to water, said that there had evidently been two kinds of fever in question, the one unequivocal typhoid and the other a "continued" fever; that not improbably they were independent in their manifestation, although the phenomena were contemporaneous. Dr. Ogleby reported a case, to which I have already made reference in other connection, in which four patients were attacked in a village near Leeds in 1876 (No. 87) after consumption of the milk of a cow which had been able to obtain only "mere sewage" as drink, the cases lingering on for months, while the cow was herself getting thinner and thinner, at last refusing to graze. After she was got rid of the disease disappeared from the house, but convalescence was tardy, though ultimately complete. But during the tedious stages of the illness one prominent feature was that of partial convalescence "by fits and starts," one day cheerfulness another day lassitude, first playfulness then a desire for rest. The dangers attending on a tedious convalescence are well illustrated by what occurred at Penistone in 1879 (No. 108), where the first case in the outbreak of 42 cases was imported from Oldham, the patient having a long convalescence, and in his movements about Penistone proving a source of danger by reason of his infectious evacuations, two of the three principal water supplies of the place being then open to excremental contamination. The second case was only made known by reason of fatality.

One special feature of note is the epidemic diarrhoea which not infrequently precedes typhoid, not only that type which is waterborne, but also the disease when originating in other ways. For instance, I may refer to three examples, far removed in time and place, and in which two causes were specially operating, namely, Perth in 1880 (No. 112), King's Lynn in 1891 (No. 182), and Shildon and East Thirsk in 1893, the latter being a case in which the disease was held by Dr. Bruce Low to be sewerborne, and disseminated also by means of milk polluted by sewer emanations. In all these three instances the disease of typhoid was preceded by epidemic diarrhoea, in Perth this milder disease being followed in the space of a week by typhoid, and at King's Lynn the preceding illness being in large amount, at Shildon it being also copious in its extent. It will be well, I think, that I should here insert a short extract from Dr. Low's report on King's Lynn as showing the character of the diarrhoeal sickness which in that town was the forerunner of the typhoid outbreak. It will serve to illustrate this phase of much typhoid that has been of late investigated with the result of finding precedential diarrhoeal illness in phenomenal amount.

"The recent epidemic of definite 'fever' was preceded by a severe and widespread outbreak of diarrhoea, which dated from the last three days of February—namely, 27th, 28th, and 29th. The diarrhoea of this outbreak attacked all classes of persons and invaded most localities in the town. Sometimes every member of an invaded household suffered. In the majority of cases the illness lasted a week or ten days; and in many cases there were along with the diarrhoea symptoms elevation of temperature and sometimes sore throat. Early

in March, with the waning of the diarrhoea outbreak, more pronounced symptoms of typhoid fever began to appear, and such cases soon became numerous. Afterwards, during April, May, and early June, though fever cases continued to occur, they were in fewer numbers, many of them being secondary cases in previously invaded houses. On my arrival in King's Lynn I learned that at the beginning of the outbreak under investigation there existed some difference of opinion as to the nature of the malady which was manifesting itself in the borough. It appears that influenza had been epidemic in the neighbourhood about the end of 1891; and when at the end of February, 1892, a sudden increase of illness accompanied with diarrhoea appeared, the opinion formed by some of the medical men was that 'gastric influenza' afforded an explanation of the symptoms. Even up to the date of my arrival in Lynn this opinion was still held by some, who contended that typhoid fever did not and had not existed in the borough. In reference, therefore, to this doubt as to the nature of the current malady, I took the opportunity, in company always with the medical men in attendance, of visiting several of the patients who were still under medical treatment. From what I saw I had no hesitation as to the disease being typhoid fever. At the same time, it is not to be denied that a number of the earlier cases failed to present in a definite way the customary symptoms of this disease, and consequently I can well understand there having been, at first, hesitation as to diagnosis. But, however this may have been, later experience of the cases induced the medical men of Lynn, almost without exception, to agree in pronouncing the current fever to have been true typhoid fever."

With reference to the above I may say that it is by no means alone in the fact of the confusion of the beginnings of typhoid being diagnosed as influenza. In many cases of late this has happened, especially where the district has been suffering under influenza. One other feature of interest which struck me was in the report of Dr. Campbell Munro, the Health Officer for the county of Renfrew, who, in reporting on an outbreak of typhoid at Paisley and Johnstone in 1893 (No. 205), stated that Dr. Macalpine, of Paisley, had found in samples of water drawn from a reservoir, the water of which was implicated, the typhoid bacillus, and that all the conditions necessary for the propagation of the bacillus were present in a bag at one end of the reservoir.

PERIOD OF INCUBATION OF TYPHOID FEVER.

The deliberations of the Clinical Society on this point are of great interest to us in connection with our subject, and it may not be out of place if I reproduce their short and pithy "Conclusions" (1892):

"1. The general conclusion to be drawn from all the facts is that the period of incubation in enteric fever varies within rather wide limits. The interval between exposure to infection and the development of distinct symptoms is probably most often twelve to fourteen days. It is not very infrequently nine or ten days, occasionally eight, and possibly even less. According to Dr. Murchison, 'it may not exceed one or two days'; but no case of the kind has been reported to the Committee. In rare cases it is prolonged to fifteen, eighteen, or even twenty-three days. Dr. Murchison thought it very doubtful if the incubation period ever much exceeds three weeks."

"2. A person suffering from enteric fever is capable of conveying the infection to others throughout the whole course of the disease, from the date of the earliest symptoms of illness until convalescence has been established for at least a fortnight."

"3. An epidemic due to milk contamination may be expected to cease at or about the end of the second week after the arrest of the contaminated supply; but an epidemic due to contamination of a public water supply may not come to an end until the fourth week after the source of specific pollution has been removed. Where an epidemic can be traced to well water its duration may be very much more prolonged, and no general statement as to the probable date of its spontaneous termination can be made."

"4. Infection can be conveyed by fomites, and retained in them, probably for two months at least."

These conclusions are backed by much evidence bearing

out their contentions, as very many of my readers will know; and it will not be necessary for me to enter into particulars as to that evidence, seeing that the volume issued by the Society is so largely known and so highly valued. But I will venture to refer to a somewhat remarkable outbreak which has been placed on record by Dr. Blaxall, of the Local Government Board for many years. At Fortune's Well, in the Isle of Portland (No. 164), there arose an outbreak of typhoid in 1886, after an absence of fifteen years, the infection being introduced by soldiers from Alexandria, 4 cases developing *en voyage*, and other 6 after landing, no one outside the regiment being attacked on board. In these latter circumstances it can only be held that infection was derived in Egypt, and, this being so, there comes the fact that the period of incubation varied from eighteen to as many as twenty-five days. Of the outbreak as it affected residents near a spring at Fortune's Well I need not speak; the facts in the appendix are clear to all as showing the source of the subsequent illness—some 80 cases—to have been due to polluted water.

SUMMATION OF THE CASE AGAINST WATER.

I think I may leave here the case against water as an important agent in the causation of typhoid, though I could fain proceed with a subject so interesting and so vital to the health of the community. I have studied to be brief; but it has not always been possible to limit myself to hard and dry facts, one and another point demanding special prominence and notice. Nor do I hold to have by any means exhausted the subject of my report; indeed, I have, perhaps, rather only touched the fringe of the matter, seeing that the question of water in relation to disease is too large to treat of within the scope of the BRITISH MEDICAL JOURNAL in the way befitting the importance of the subject. But let it suffice that I have endeavoured to show in what way I consider water to have played its part in the causation and dissemination of typhoid as we have been used to see it in our own country. It will have been observed that I have not travelled beyond the confines of the United Kingdom for instances of waterborne typhoid, deeming it best to confine my report to the British Isles. And truly I have not found much trouble in discovering the material on which to base my conclusions. In the period of less than forty years which I have selected for the purposes of my summary tables I have, as already pointed out, laid under contribution the reports of no fewer than 206 distinct outbreaks in which water has proved a factor in the spread of typhoid fever; and it is by no means in the earlier years of this period that I have found the disease thus to be prevailing. Analysis of the chronological column displays the significant fact that in the last fifteen years as many as 105 of the total find place. The reason of this I shall hope shortly to show.

In having thus brought together what I may claim to be a unique collection of waterborne outbreaks, I make known my indebtedness to the literature emanating from the Medical Department of the State, at Whitehall, the reports of which Department I have, in an especial manner, laid under contribution in my summary. And again, it will be noticed that in illustrating my points I have in large measure confined myself to references to reports issued from the Public Health Department, not for the reason that there are not reports from others to which I could have referred, but because the inquiries held by that Department have in most cases been carried out with an amount of detail and width which has been next to impracticable on the part of local health officers, hampered as they are with much work, and moreover as their experience has for the most part been on matters of disease causation when elaborate and sustained inquiry has been called for in the elucidation of some obscure point. This is no discredit to the local officers, but it is a reason for the prominence which is here given to reports issuing from Whitehall. It has been impossible for me to escape from the fact that nearly all the great epidemics of typhoid fever which have occurred from time to time in our country, have called for the intervention of the Department of State Medicine. And one can well see that a body of men trained as is the small body at Whitehall must needs have a grasp of subjects connected with their particular branch of research far and away beyond the comparatively circum-

scribed experience which pertains to the local officers of our sanitary districts, especially in view of our present pernicious system of short tenure, bad pay, and do-the-least-possible policy. And I would here pay my humble tribute to the excellent series of reports which continue to issue from the Medical Department at Whitehall, concerning local prevalences of infectious disease in England and Wales—a series unique in the whole world, and unsurpassed by any nation. Under the successive leaderships of Sir John Simon, the late Dr. Seaton, Sir George Buchanan, and more recently and at the present moment of Dr. Thorne Thorne, we have seen immense strides made by the sanitary bodies of the country towards the perfecting of our sanitary system: the progress being in no mean degree due to the indefatigable labours of these leaders of sanitary science to educate the people to a just idea of the importance of all that goes to make health, alike for the individual and the people at large. The careful and elaborate reports which emanate from the pens of the medical staff of the Local Government Board are worthy of emulation, and they were never abler or more appreciated than to-day. These reports find an honoured place in the library of the British Medical Association, and I acknowledge the vast assistance which these classic documents have been to me in my present paper, easing my inquiry to no mean extent by their clearness and precision.

There may be found those who will attempt to argue that waterborne typhoid is a watchword of a particular section of the public during a comparatively recent period; that the theory is one that has not received the approval of some men of unquestioned scientific attainments. It may be so to some extent. But why? As to the first point I agree that it is in the last fifteen years or so that the theory has come into greater prominence, but the reason is not, to my mind, far to seek. Prior to and during the seventies, whenever an outbreak of typhoid fever had to be investigated, there was as a very general rule a desire on the part of the Government to show up the insanitary circumstances with which the disease had been associated rather than to elaborate the inquiry with a view of differentiating between the potency of one and another possible cause of the disease; so that while there was seldom little doubt as to the relation of the disease to insanitary conditions in a general sense, there was not often any very pronounced thesis advanced as to the part played by any one of the many possible causes. True, the summary tables show that my statement can be brought in question in many instances, but taken as a whole the inquiries of earlier years did not proceed to an elucidation of the precise manner of propagation of the fever. It has thus come about that I have waded through numerous reports to no purpose, seeing that though there was undoubted possibility that water had been a factor, more or less special, in the causation of a particular epidemic, there was no definite and detailed consideration of the part played by water. Notable cases wherein the disease was traceable to water are of course to be readily found, or my summary table would not have assumed its present bulk in regard of the earlier years of the period covered. But it is apparent to me that in the latter fifteen years, roughly, of the period there has been a manifest and ever growing tendency to push the matter of cause as far as possible in order that the local health body might be enabled to lay their hand, so to speak, on the spot and heal it, the weakness of their sanitary defence being thus held up to the light of publicity, and its strengthening as matter of course thus more easily brought about. Indeed, it is this excellent method of holding up recalcitrant sanitary authorities to the public gaze that has undoubtedly done much to stimulate them to sanitary activity. Next to threatened dissolution there seems to be no step so calculated to stir a body into activity as public opinion.

In this way, then, has it come about, to my mind, that we hear to-day so much more concerning waterborne typhoid than we did twenty years ago. Had inquiries always been conducted on the plan now commonly adopted at Whitehall, I do not for one moment doubt that my summary tables, already lengthy, would have been much distended from their present shape. But the labour entailed in the process of exclusion of those outbreaks in respect of which the reports were so meagre as to necessitate omission of them from my press, has been very great; how great may to some extent be

gathered from the fact that in the four years 1870-73 the Medical Department at Whitehall chronicled no fewer than 148 inquiries made by their staff into separate outbreaks of typhoid fever; and it was essential that all these, or such majority of them as found place in accessible reports, should be studied for the purpose of seeing in which of them water had been shown to have had a part in the causation or spread of the disease. But however loud is the outcry in some quarters on the subject of waterborne typhoid, I hope that the most sceptical hitherto on the matter will have been convinced by a perusal of the preceding pages of this report that the case against water as a disseminator of typhoid fever has been fully made out. My aim has been to place the question beyond the pale of doubt. I shall be more than rewarded if I have succeeded in my object.

What have the pages of my report shown? They have shown typhoid fever caused and spread in a variety of ways by the agency of water; they have testified to the fact that water can become polluted at its source, on its way to the consumer (alike before and after entry to the distributing mains), and within the precincts of the domestic dwelling. We have seen outbreaks caused by polluted wells, by sewage-contaminated rivers and streams, by water services which have received the drainage of manured fields, the sewage of whole villages, and innumerable excremental pollutions over the areas of the gathering grounds; by the careless laying, in close proximity and in badly jointed fashion, of watermains and sewers (the former sometimes even passing through the latter); by the washing of milk cans with polluted water; by the mixing of milk with water equally polluted; and by numerous other ways, all of which are set out in my report under their respective headings. I need not here enlarge on the matter; let the facts in my tables and the illustrations therefrom, with which I have striven to picture my several points, suffice.

For the rest, it seems necessary only that I should consider briefly the points which the foregoing pages show to be those which should engage the attention of sanitarians in the future if a continuance of the constantly-recurring outbreaks of waterborne typhoid fever is to be prevented.

THE OUTLOOK: SOME POINTS FOR FUTURE CONSIDERATION.

My study of the subject dealt with in this report has led me very strongly to support the theory that sees in the soil the natural habitat and breeding ground of the bacillus of typhoid fever outside the human body. This belief in no-wise lessens my regard of the disease as being largely caused by water—rather the reverse. We are most of us aware of the possibility of transmission of tetanus to man from the lower animals, as, for example, by a kick from a horse. Yet the bacillus of tetanus lives in the soil. It is taken up by the hoof of the quadruped, and the animal is thus made the medium of transmission of the malady induced by the organism. I do not myself incline to the belief that the bacillus of typhoid fever is conveyed to man by the medium of water, save in so far as the bacillus has gained access to the water by excremental pollution from soakage or the like. Certain it is to my way of thinking that the essential element in the prevention of waterborne typhoid fever is cleanliness. All that goes to cause pollution of the soil tends to foster disease. No point is so strongly or so persistently brought out in the history of typhoid fever occurrences in our country as that dirt and disease go hand in hand. Only in the case of rivers does man seem to place his excrement directly into his own or his neighbour's drinking water, but he does not scruple in only too many instances to so dispose of his filth that it must in the natural order of things find its way to that drinking water. It is not alone in our rural and sparsely-populated districts that such disposal takes place; it is just as common to see people harbouring up their filth in proximity to dwellings and local water supplies in our towns. Those abominations which to-day persist in so many of our towns—leaky and huge midden privies, uncovered and ill-constructed ashpits, cesspools permitting soakage of their contents, no one knows where—all these and more are the accompaniments of daily life in scores of towns. And where town populations have the good sense to so dispose of their filth as not to poison the air they breathe or their local wells, too often we find them in their selfishness and negligence

endangering the water service of a vast aggregation of people in some adjacent city or borough by so ridding themselves of their excrement as to pollute a gathering ground or a stream or river used for purposes of domestic water supply.

WHAT IS THE REMEDY? I WILL ATTEMPT THE ANSWER.

1. *Local Water Supplies.*—I would see carried out in their entirety, so far as is at all possible, the recommendations of the Committee appointed by the Local Government Board in 1875 to inquire into the various methods of sewage disposal, where they suggest ridding the country of cesspools in the midst of towns; and would also see cesspit middens improved off the face of the earth. I would see the conclusion of the Society of Arts Committee on the Health of Towns of 1876 carried out—namely, that all middens, privies, and cesspools in towns should be abolished by law, feeling that these disease-disseminating abominations as we permit them to-day are annually costing the country enormous sums by these very qualities of disease provocation. To this end I would see the statutory duty of sanitary authorities to make provision of proper sewers for their districts enforced in all cases where sewerage is practicable. There will probably always be found reason for retaining some form of storage of excrement and refuse near dwellings for a time in the case of rural localities, but only in such places. And here we see the wisdom of the excellent series of model by-laws which have been drawn up by the Local Government Board for the guidance of local authorities who desire to secure for their constituents the minimum of danger from use of these receptacles. Thus the by-laws prescribe the method of construction and position in respect of water supplies of such receptacles as midden privies, ashpits, earthclosets, cesspools, and the like; and it will be well when by-laws come to be adopted by sanitary bodies, and in turn enforced where thus adopted. It is one thing to have an admirable series of safeguards at hand, and another to see to it that those safeguards are made to apply. It will, however, not be enough that cesspools and such like be abolished; it will be necessary also that the old disused forms of excrement disposal be so done away with as not to prove dangers by reason of their condition at the time of abolition. So I would see the application of some powerful disinfectant to the receptacles when emptied finally, as well as the complete filling in of the space occupied by them, in such manner that no danger shall accrue to water supplies by reason of future soakage of filth left in the middens, etc.

But there is another side to this question of local supplies, and that is that wells from a subsoil liable to pollution should in no wise be made use of as sources of water supply. The soil on which many of our towns are built has been subjected to gross contamination for many years, and it is not to be thought of as likely that the mere abolition of cesspools, and so forth, will at once render safe the abstraction of water from wells sunk in their proximity. Indeed, it may well be that no return could with safety be made to wells circumstanced as they are in some places; whilst in others it will take a long time to rid the soil of its accumulated filth. It is, however, obvious that many wells to-day in our country are not only so circumstanced as seriously to threaten the health of consumers of their contents, but also that the wells are constructed in such fashion as to permit of soakage from the surrounding soil into them, both surface and subsoil drainage. It should therefore be the aim of all sanitary bodies to secure the internal lining of wells being so finished as to prevent the ingress of water from any questionable source. I have already given Professor R. Koch's method of securing wells against pollution. I say nothing concerning it. But I do impress upon health bodies the necessity of seeing to it that wells in the areas of their jurisdiction are not allowed to remain in a condition favouring their pollution by water of doubtful quality. The further danger of contamination of well water by reason of rain storms and resulting floods is one to be thought of; and one that calls for the proper construction of well mouths, lest they be subjected to periodical overflow by surface water of polluted character. It would seem, then, that middens and other similar structures will be at times a necessity, and it also seems that wells will be still more of an essential element in rural life; the condition of cleanliness necessary to guard against pollution of the one by the other should be aimed at, therefore, in all

places where these methods of disposal and supply obtain.

The sanitary authorities of rural districts have an excellent power in their hands for the inspection of water supplies in the areas over which they have jurisdiction under Section 7 of the Public Health (Water) Act, 1878, and it would be well if more use were generally made of the power thus conferred upon them. Not that I would be thought of as holding the view that rural water supplies are not subject to scrutiny; what I have in my mind is the desire to see practical use made of the inspectorial duty cast upon rural authorities. It will often happen that action can be taken on inspections carried out with the object of securing wholesome for impure supplies, and much more can be done in the direction of closing polluted wells and the like than has been effected in the past. I am of course well acquainted with the difficulties in the way of securing the closure of polluted wells, and I would welcome the alteration in the wording of Section 70 of the Public Health Act, 1875, from "injurious to health" to "dangerous to health" in accordance with the prayer of the Society of Medical Officers of Health and of Public Analysts presented some time back to the Local Government Board. The action as it stands has oftentimes proved an obstacle in the way of closure of wells undoubtedly "dangerous" to the health of consumers of their contents.

Before I leave the region of domestic supplies there is one other point which I would like to name, and that is the danger of continuing anywhere the flushing of waterclosets directly from water mains. I know that the practice is by no means so common as it was twenty years ago, but it is far from uncommon even yet. Not only should a cistern be used for the purpose of flushing, but a separate cistern to boot, since it may well be that a cistern common to the whole house will be contaminated by the passage of air from the closet pan up the pipe, the liability to this form of pollution being obviated by the intervention of a separate flushing cistern. It may be argued that a sanitary authority has no power to compel the provision thus of flushing apparatus to existing closets. I am only sorry that it is so. The sooner the omission is rectified by the adoption of the Public Health Acts Amendment Act of 1890 the better. At least let health bodies see to it that all closets hereafter erected are so furnished. I would also see the covering and frequent cleansing of house-supply cisterns insisted upon.

I know that in thus leaving this important section of domestic water service I am going from it with but poor attempt to emphasise the needs of the community at the present time for the perfecting of such service; but if my remarks attract attention to some of the most pressing wants, I shall have achieved something. The foregoing pages testify to the terrible consequences of neglect of elementary principles of domestic cleanliness in the past; let them enforce the lessons so slow of being learned.

[To be concluded.]

BRITISH MEDICAL ASSOCIATION.

SIXTY-THIRD ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION IN LONDON, 1895.

THE MEDICAL INSTITUTIONS OF LONDON.

(Continued from page 136.)

THE HOSPITALS WITH MEDICAL SCHOOLS.

By D'ANEY POWER, M.A., F.R.C.S. Eng.,

Demonstrator of Surgery at St. Bartholomew's Hospital, and Surgeon to the Victoria Hospital for Children.

The hospitals in London, like those throughout England, Scotland, and Wales, are remarkable in that they are not endowed by the State. A few have large revenues derived from landed property or from funds obtained from private munificence. The rest, and these are by far the greater number, derive their income from subscriptions contributed

annually and in small sums by large numbers of private individuals.

The hospitals are divisible into two great groups, those which have a medical school attached and those which have no regular medical school, though students may and often do attend them.

Every hospital has a visiting or consulting staff, of whom the seniors take charge of the patients admitted into the hospital, whilst the junior members are occupied in attending to the out-patients. Each hospital also has a resident staff, consisting of recently qualified practitioners, who are elected to hold their office for a term of six months or a year. The visiting staff in the larger hospitals to which medical schools are attached act as teachers by lecturing and giving instruction at the bedside.

The nursing in nearly every hospital is unsectarian. It is carried out by a matron, who exercises a general supervision and by a head nurse for each ward, who is usually called "the sister." Each sister has to assist her own or more properly-certificated nurses and a subordinate group of nurses, or "probationers," who are being taught their duties. The matron and the sisters are more or less isolated, but the nurses usually live in common.

Each hospital is governed by a lay committee, consisting either of the whole body of subscribers or of a certain number to whom the larger body delegate their authority. The Committee usually possess two permanent officers, the Treasurer and the Secretary. The power of appointing all the officers of the hospital is vested absolutely in the lay Committee.

The hospitals to which medical schools are attached are twelve in number. Two of these are almost coeval with the Norman conquest of England, whilst the remainder originated under a variety of circumstances either in this or in the previous century.

ST. BARTHOLOMEW'S HOSPITAL.

St. Bartholomew's Hospital, in West Smithfield, stands near St. Paul's Cathedral, upon the site which Rahere, its founder, acquired for it in 1123. Rahere afterwards founded the neighbouring Priory of St. Bartholomew, and became its first prior. The hospital, however, had an independent constitution and a separate estate, though it was for some purposes under the control of the Priory. It had a master, eight brethren and four sisters, the community being subject to the rule of St. Austin. It was a hospital from the beginning, and not a mere almshouse. St. Thomas Becket, the great Archbishop of Canterbury, was one of its early benefactors.

The hospital had an uninterrupted existence until the dissolution of the Priory in 1537. It then passed with its revenues into the possession of Henry VIII, who refounded it by Royal Charter in 1544, at the petition of Sir Richard Gresham, Lord Mayor of London, and father of that Sir Thomas Gresham, who built the Royal Exchange. A fresh Charter was granted in 1547, giving back to the foundation the greater part of its former revenues. It then contained 100 beds, it now has a service of 700 beds; there were then but few out-patients, they now amount to more than 175,000 annually.

For many years the hospital seems to have been a group of detached buildings. The majority of these disappeared about 1725, to make way for the present quadrangle, built by Gibbs in 1730. The main entrance, however, remains where it has always been, and although it was rebuilt in 1772 and was closed for many years, we can think as we pass through it that it was traversed 770 years ago by men whose fathers saw William the First enter London as a conqueror. It witnessed a notable sight on Saturday morning June 13th, 1381, for Wat Tyler, by altercation with the king (Richard the Second) in the open space which still exists immediately in front of the hospital, so enraged the Mayor, William Walworth, that he arrested him on the head with a sword blow. Whereupon Wat Tyler furiously struck the Mayor with his dagger, but hurt him not, by reason he was well armed. The Mayor, having received his stroke, drew his basilard (or long dagger generally worn suspended from the girdle, which when decorated with silver, could only be "carried by those possessed of a yearly income of £100) and grievously wounded Wat in the neck, and withal gave him a great blow on the head. Wat, spurring his horse, cried to the commons to

revenge him. The horse bore him about eighty feet from the place, and there he fell down half dead; and by-and-by they which attended the king, envied him about so as he was not seen of his company. Many of them thrust him in divers places of his body, and drew him into the hospital of St. Bartholomew, from whence again the Mayor caused him to be drawn into Smithfield, and there to be beheaded."

The hospital still presents many features of interest attesting its ancient and, in many respects, unique position. It forms a parish in itself, and has within its walls a small parish church served by the Vicar, or as he is known technically "the hospitalier." It possesses, too, a large hall, to which access is obtained by a noble staircase whose walls are ornamented with frescoes painted by Hogarth. The hall itself contains numerous paintings, some of a very high order of merit, notably the picture of Percivall Pott, by Sir Joshua Reynolds, and of Abernethy, by Sir Thomas Lawrence.

The liberality of its late Treasurer, Sir Sidney Waterlow, long provided the hospital with a most suitable and efficient convalescent home at Highgate, but the munificence of Mr. Kettlewell superseded this home by a much larger one at Swanley in Kent. It was opened on July 18th, 1885.

The school is a large one, and is accommodated in buildings which are leased from the hospital authorities. There is a good library and a splendid museum, both deserving of a visit.

The hospital and school have been well and ably served by a long succession of illustrious men, amongst whom William Harvey, David Picaire, William Clowes, and Percivall Pott are accounted the chief ornaments. The whole neighbourhood of the hospital is classic ground, and the visitor to the hospital should not omit to visit the priory church of St. Bartholomew-the-Great, which lies within two minutes' walk of the church of St. Bartholomew-the-Less. Midway between the two churches, and let into a part of the wall of the hospital is a tablet marking the site of the stake at which Henry VIII burnt those who denied his ecclesiastical supremacy, Mary burnt Protestants, and Elizabeth, her sister, burnt Anabaptists.

ST. THOMAS'S HOSPITAL.

St. Thomas's Hospital has nearly as great an antiquity as that of St. Bartholomew's, and, like it, took its origin in that great philanthropic movement started by Lanfranc, the Norman Archbishop, about the year 1100. It has been less fortunate than St. Bartholomew's, however, for it has changed its name, its site, and has lost many of its revenues.

The exact date at which the original hospital was founded is unknown. It belonged to the canons of the Priory of St. Mary Overy at the foot of London Bridge, and it was burnt about 1207 by the fire which destroyed a great part of Southwark and extended over the bridge into the city of London. The first hospital being thus destroyed the prior and convent immediately proceeded to erect a second hospital upon the old site (now covered by the Bridge House Hotel and the Westminster Bank) upon the west side of London Bridge, a convenient position, for it was immediately by the side of the great road leading into Kent and extending from Dover to Wrotham. This building was used temporarily for religious purposes and mass was said there until the priory could be rebuilt. Peter de Rupibus, Bishop of Winchester, in 1228 began to build a new and larger hospital, which he placed on the eastern side of the Watling Street, a position which the hospital maintained until it moved to the foot of Westminster Bridge, when the land was bought for the London Bridge railway station in 1865. The hospital thus built was assisted by Bells from the various Popes and obtained valuable grants of land. Many of these grants show that it maintained its ecclesiastical character until quite late in its history, for they were bequests of property made by individuals in exchange for lodgings, living, and pious observances within the precincts of the hospital. Thus the master and brethren in one case agree to find for Alicia within the court of the hospital a suitable bed with everything necessary to a bed for her so long as she lives; she is to have good service and money for clothing and fuel, but is to make no further claim of any kind. The hospital was dedicated to St. Thomas (Becket) the Martyr, and it was rendered independent of the priory to which it had at first owed its support. It was sometimes known from

its patron saint as "Bekket's apytell." In later years it was the hospital of the Holy Trinity, a title which gave place to the "King's Hospital," out of compliment to Edward VI, its refounder; finally it was called the Hospital of St. Thomas the Apostle. It consisted, like the Hospital of St. Bartholomew's, of a custos or master, of brethren, and of three lay sisters, who, in 1535, had the charge of forty beds for poor and infirm people who were to be supplied with food and firing.

The hospital was surrendered to the King at the dissolution of the monasteries in 1538, and, although some efforts were made by Gresham to refund it, nothing was done effectually until the citizens of London, aided and encouraged by Bishop Ridley, took the matter in hand, when King Edward VI granted letters patent to it in 1553 and endowed it with 4,000 marks by the year.

The third hospital—built in 1228—became so ruinous and deficient that it was rebuilt a little nearer to Tooley Street about 1507. This hospital was in many respects a poorhouse rather than a true hospital, but in 1571 Mr. Bull was appointed physician to the hospital at a salary of 20 marks a year, whilst the surgeon was paid for those cases which he cured. A few years later there was an apothecary and herb-woman, who received £4 a year for physical herbs, whilst in 1652 a midwife was paid 2s. 6d. for her help to two poor women. The status of none of these officers was high; they were all subordinate to an official governor, whilst the surgeon ranks between the shoemaker and the barber. Two "fitting ministers" were appointed: one for the poor and officers of the hospital, who was called "the hospitalier;" the other was for the parish of St. Thomas's Hospital. The hospital had again fallen into decay in 1694, after it had been extensively used as a military and naval hospital for the reception of soldiers and sailors wounded in the Dutch war. It was rebuilt by the energy of Sir Robert Clayton, the "Ishban" of Dryden's *Absalom and Achitophel*, whose statue still stands outside the present medical school buildings in Lambeth, and the first mention of a medical school occurs about this time.

The fame of Cheselden and of Mead raised the school to a first-rate position, but the internal dissensions were so great that its prestige soon began to decline, in spite of the fact that it entered into an alliance with Guy's Hospital, by which the students of one hospital attended the practice of both, and although Sir Astley Cooper—the most popular and influential man in his profession—was attached to it for many years as lecturer on anatomy.

The separation between Guy's and St. Thomas's Hospitals took place in 1824, and St. Thomas's remained in the Borough until 1865, when its site was required for the London Bridge railway station, and was sold for a sum of £300,000. The hospital was then accommodated temporarily on the site of the Surrey Music Hall until the new buildings were finished in 1870/71. These buildings are situated at the foot of Westminster Bridge, and close to Lambeth Palace, the seat of the Archbishops of Canterbury. The hospital now faces the Thames, and consist of eight distinct buildings or pavilions, containing three tiers of wards above the ground floor, and coupled together by a double corridor. The school buildings are situated at the west end of the block, and contain a first-rate museum. Amongst the many notable men who have been attached to St. Thomas's Hospital, none, perhaps, are more notable than Sir Gilbert Blane and Sir John Simon, the pioneers of sanitary science in this country.

GUY'S HOSPITAL.

Guy's Hospital arose directly out of St. Thomas's Hospital, and for many years remained intimately associated with it. Thomas Guy, a wealthy and benevolent citizen of London, had aided materially in the expense of rebuilding a part of St. Thomas's Hospital at the beginning of the eighteenth century. Early in 1721 the records of St. Thomas's Hospital contain the following minute: "Our worthy governor and benefactor Thomas Guy, intending to found and erect an hospital for incurables, in the close of this hospital, in the parish of St. Thomas, we have agreed to grant him a lease.....of several parcels of ground at a ground rent of £17 14s. per annum....." A design was procured from Mr. Lane, an emi-

nent architect and surveyor, and the building was carried out so rapidly that it was roofed in before the death of the founder on December 27th, 1724. In a little more than a week after his death Guy's Hospital was opened, and on January 6th, 1725, sixty patients were admitted. The governing body was incorporated by Act of Parliament in 1725, with a president and treasurer as permanent officers. Two physicians and two surgeons were appointed in May, 1725, to take charge of the patients, a matron, eleven sisters, and eight nurses having been appointed a few weeks earlier. The medical school attached to Guy's very soon rose into repute, and it has always been maintained in a state of the highest efficiency. One of the earliest public courses on anatomy and surgery was that given by Samuel Sharp, surgeon to the hospital from 1733 to 1757. The great repute of the surgical and anatomical teaching was maintained by Sir Astley Cooper, and in later years by John Hilton. The long line of physicians has been even more distinguished than that of the surgeons, and is certainly the noblest list possessed by any hospital in London. Wollaston and Bright, Addison and Golding Bird, Gull and Habershon, Moxon and Hilton-Fagge, not to mention those who are happily yet alive, followed each other in a remarkable succession. It is not surprising that the students flocked to such teachers, and that in spite of those unseemly disputes and of the lives too soon cut short, which a few years ago threatened to sap the vitality of the school, Guy's Hospital now boasts one of the largest and most active of the metropolitan schools of medicine.

The connection between St. Thomas's and Guy's Hospitals was most intimate between the years 1768 and 1824, and it was then that the terms "The Borough Hospitals" and "The United Hospitals" came into use. The surgical lectures during this period were given at St. Thomas's Hospital, and the medical lectures at Guy's; and the students of each hospital had the right to attend the practice and teaching at the other. Some friction eventually arising between Sir Astley Cooper and J. H. Green, Mr. Harrison, the autocratic treasurer of Guy's Hospital, took the matter into his own hands, and built a separate medical school for the students of his hospital, which was in use on June 21st, 1826. The privilege of attending the practice of the two hospitals remained until December, 1836, when the students themselves came to loggerheads, and the arrangement was formally cancelled.

The hospital is an interesting one as it now stands, for it is a unique combination of the new and of the old. Its laboratories are excellent. The museum contains a most remarkable collection of models in wax representing very various pathological conditions. They were made by Mr. Towne, who spent his life in bringing his curious art to perfection. The school is further noteworthy for the special attention which it has recently given to the instruction of dental students.

THE LONDON HOSPITAL.

The London Hospital contains 786 beds, and being situated in Whitechapel, near the docks and in the poorest part of London, it has perhaps greater clinical resources than any of the metropolitan hospitals. It commenced its existence in 1740 as a small infirmary in Featherstone Street. It was then moved to Prescott Street, Goodman's Fields, a neighbourhood inhabited then, as now, by a large Jewish population. Additional accommodation was soon required, and buildings were erected in 1757 upon a portion of the site which the hospital now occupies, and about this time the governors were incorporated by a Royal Charter. The west wing was opened in 1831, the east wing a few years later, and further improvements have recently been made, so that the hospital now boasts itself the largest in Great Britain. The medical school began when the first student was admitted in January, 1741. Mr. Harrison in 1749 obtained permission of the hospital authorities to deliver a course of lectures on surgery within the hospital, and a similar permission was accorded to Mr. Thomson in 1755. This school was therefore one of the earliest in England. Isolated courses of lectures gave place in 1783 to systematic instruction carried out in a building erected for the purpose, and chiefly at the expense of Sir William Blizard, one of the most active surgeons of his day. The hospital is well

worthy of a visit; although it is situated in the heart of the most populous part of London, it has contrived to retain a considerable amount of garden. It has an excellent museum, and splendid accommodation for students. It has always been the home of good clinical teaching, for a course of lectures on clinical medicine were given in 1792, and were successfully resumed after an interval by Dr. Billing in 1822. Here, too, about 1773 Mr. Henry Thomson (surgeon to the hospital 1753-1780) amputated the hip for the second, or if his case was later than Perrault's, for the third time in the history of the operation.

Sir Andrew Clark and Sir Morell Mackenzie have been attached to the hospital as physicians. John Scott, from whom are derived Scott's dressing and ointment; Curling, Critchett, and Jonathan Hutchinson, amongst many other illustrious men, have been surgeons.

THE WESTMINSTER HOSPITAL.

The Westminster Hospital, situated in Broad Sanctuary, under the very shadow of Westminster Abbey, is remarkable as being the first general hospital founded, and entirely supported by voluntary contributions. It was originally established in 1719 by several individuals, who had previously made common cause for the relief of sick prisoners in Newgate, the Clink, and other prisons of the metropolis. A house was taken in Petty France, now called York Street, on March 25th, 1720, and patients were admitted upon the following May 11th. This hospital was known as the Infirmary for the Sick and Needy, and was established in the midst of one of the poorest and most neglected neighbourhoods of London. It at once received the support of the two sergeant-surgeons to King George I, Claudius Amyand and Ambrose Dickens. Its usefulness was so great that in 1724 a larger house, capable of containing sixty beds, was rented, and at the same time Cheselden was appointed principal surgeon, whilst "the princely" Mead became its consulting physician. The infirmary again outgrew its accommodation, until in 1733 it became necessary to find larger premises. The majority of the governors determined to purchase a house in James Street, but a small and influential minority were dissatisfied with this decision, as they held that Lanesborough House, at Hyde Park Corner, offered a better site. A split took place. The infirmary was established, with 100 beds, in James Street, and was opened in January, 1733-34. The dissatisfied minority bought Lanesborough House, and opened it on January 1st, 1733-34, with 30 beds, thus laying the foundation of the noble institution now known as St. George's Hospital. It is interesting to notice that the consulting physician and the three principal surgeons of the Westminster Hospital were amongst the seceders. In 1754 the Westminster Infirmary became the Westminster Hospital, but it continued to occupy the same position in James Street until 1834, when the buildings had become so dilapidated that the hospital was moved into the one which it now occupies in Broad Sanctuary, where in 1836 it obtained its charter of incorporation.

The school attached to the hospital has led a most chequered existence. The hospital was utilised for clinical instruction from its foundation, but, at any rate, during the early part of the present century the students had to obtain their systematic instruction as best they could, usually by attending one of the private schools. An abortive attempt was made to found a school in direct connection with the hospital in 1833 again by Guthrie in 1834, and again later, but it was not until 1841 that the Westminster Hospital School of Medicine was formally established, only to fail through again in 1847, when the College of Surgeons withdrew their recognition of the anatomical lectures in the school. The students were therefore transferred for this branch of their teaching to King's College. The school, however, was soon reorganised, and was carried on in spite of most disadvantageous surroundings by the self-denying labours of Basham, Heath, and Fowler. The matter was at last taken in hand, and proper accommodation was provided in 1885 by building suitably large premises in Caxton Street, a short distance from the hospital, and the school, in the hands of an energetic staff, is now worthy the hospital to which it is attached.

ST. GEORGE'S HOSPITAL.

St. George's Hospital, as we have seen, originated in a schism amongst the governors of the Westminster Infirmary in 1733. The seceders maintained that Lanesborough House was better adapted for a hospital than any other available site "on account of the strength of the building and of the airiness of the situation," whilst the majority of the governors thought that Hyde Park Corner was too far away from Westminster to render a hospital there of much service to the people whom it was their design to benefit. The scheme was well supported. Mead and Sir Hans Sloane took a personal interest in the well-being of the new institution, and it was opened with thirty beds, soon afterwards increased to sixty, on January 1st, 1733-4.

The work of the hospital was carried on so successfully that it was soon found necessary to alter the buildings to fit them for maintaining 300 beds. In this state the hospital continued without material alteration until 1825, when a new one was erected immediately behind Lanesborough House. The new building was finished in April, 1831, and was adapted to receive 325 in-patients. It had a theatre for lectures and a museum for pathological preparations. In June, 1831, an Act of Incorporation was obtained empowering the trustees of the hospital to hold property to the amount of £20,000. The hospital has also been particularly fortunate in having the Atkinson-Morley Convalescent Home attached to it.

The staff of St. George's Hospital has at all times been peculiarly rich in the possession of men of the widest scientific attainments and of far more than local reputation. John Hunter, Matthew Baillie, William Hecroden, Thomas Young the physicist, Cheselden, and the various members of the Hawkins family, Sir Benjamin Brodie, and Prescott Hewlett represent but a few of the illustrious names on its roll. The medical school was not established until 1831; before that time the students of the hospital attended the necessary lectures in the Great Windmill Street School, which originated with John Hunter, and was carried on by a series of St. George's men, whilst at a still later time they were taught anatomy by Mr. Lane at the Grosvenor Place School. Mr. Lane was harshly treated by a part of the staff of St. George's Hospital, and a separation between his school and the hospital became inevitable. The hospital, therefore, secured dissecting rooms in Kinnerton Street, which were long of the greatest service, though they have lately been rendered unnecessary by the recent additions to the hospital buildings.

ST. MARY'S HOSPITAL.

St. Mary's Hospital arose out of St. George's Hospital in much the same manner as St. George's had itself arisen from the Westminster Hospital. It practically owes its origin to the zeal and ability of Mr. Samuel Armstrong Lane, who died in 1892 at the mature age of 90. Lane was for many years the most able teacher at the Grosvenor Place School of Medicine, where many of the students of St. George's Hospital were taught. He was an accomplished anatomist and a skillful surgeon, yet when he applied for an appointment as assistant surgeon at St. George's Hospital he was rejected in favour of one who, though much his inferior, was a relative of Sir Benjamin Brodie. Lane, nothing daunted, determined not to offer himself again, but to start a rival hospital. The project was mooted in 1843, the first stone was laid in 1845, and the building was opened with accommodation for 50 patients in June, 1851, when Mr. Lane was appointed one of the surgeons. The governors of the hospital were able to open wards for the reception of 150 patients in June, 1852, as this was the full complement of the hospital. The original building was at first called the Marylebone and Paddington Hospital, though it very soon acquired its present name. The hospital stands in Cambridge Place, close to the Great Western railway station, and on a site which once formed the reservoir of the Grand Junction Waterworks. It has not yet obtained any charter or Act of Incorporation. The medical school attached to the hospital was opened in 1854. Both the hospital and the school have recently undergone great improvements, for they are happy in possessing one of the most energetic teaching staffs in London. The medical school contains a remarkably complete museum of pathology.

CHARING CROSS HOSPITAL.

The Charing Cross Hospital began its career in 1815 as a dispensary in the house of Dr. Benjamin Goding, first in Leicester Place and afterwards in St. Martin's Lane. It assumed the name of the West London Infirmary about the year 1818. Mr. Pettigrew became attached to the institution about 1819 and it was doubtless by his influence which he exercised that it obtained the patronage of the Duke and Duchess of York. The Committee took a house in Vinthers Street, near Charing Cross, in January, 1823, and out-patients were seen there until 1827, when the name was changed to Charing Cross Hospital, and arrangements were made to provide twelve or fifteen beds for use in cases of emergency. Dr. Gabriel Sigmund became a physician to the dispensary about 1825 and it was mainly owing to his energy in collecting and contributing money that the dispensary became converted into a hospital. The hospital soon outgrew its accommodation, and, a site having been obtained where the present hospital stands, the foundation stone of a new building was laid with full Masonic ceremonies on September 15th, 1831. The design was furnished by Decimus Burton, and the hospital was opened in February, 1834, a medical school being inaugurated in the following year.

The medical staff had serious disagreements in 1835-36, which terminated in the resignation of Dr. Sigmund and Mr. Pettigrew, the cause of dissension being the condition of the school, which seemed, to some members of the staff, so bad as to require an amalgamation with its somewhat more prosperous rival at King's College. About this time, too, the Council of the Royal College of Surgeons took away from the hospital their recognition of it as a medical school. The school recovered itself in due course and was again allowed to become a teaching body. The hospital was entirely rebuilt in 1876, was enlarged in 1887, and the Out-patient Department has since been remodelled.

The Medical School is separated from the hospital by the width of the roadway, the two buildings being connected by an underground passage. It was rebuilt in 1881, and is very conveniently arranged. Its proximity to the Dental Hospital in Leicester Square has rendered it necessary for the school to give special facilities to students requiring systematic instruction for the diploma in dental surgery.

THE MIDDLESEX HOSPITAL.

The Middlesex Hospital was founded in 1745 under the name of the Middlesex Infirmary. It consisted at first of two dwelling-houses, situated in Windmill Street, Tottenham Court Road, rented from Mr. Gedge, one of the early governors. It only contained six beds for the first two years after its foundation, but on November 11th, 1746, it assumed the name of the Middlesex Hospital. The first midwifery patient was admitted on June 29th, 1747, and soon afterwards the governors directed that a board should be put up at the end of the street "in a cheap and frugal manner inscribed with the following words: Middlesex Hospital for Sick, Lame, and Lying-in Married Women." The notice broke "Priscian's head," for it was thoroughly ungrammatical, but it doubtless served its purpose of drawing attention to the charity. The midwifery department at first threatened to swamp the other cases, but by the adoption of radical measures this was eventually prevented, though the cases remained so numerous that on May 15th, 1755, the first stone of a new and larger hospital was laid by the Earl of Northumberland in the Marylebone Fields, on the site of the present building. The transfer of patients appears to have taken place between August 30th and September 6th, 1757. A west wing was added to this building in 1770, and the wards, which had hitherto been known by the names of the sisters tending them, were given permanent names. The finances of the hospital were in so flourishing a state that it was proposed to erect an east wing in 1775; at this time, too, and for many subsequent years, the hospital garden was a conspicuous ornament. The expense of the new building proved too much for the resources of the hospital, and it passed through a long period of financial depression from 1781. It was not until January, 1824, that its condition was sufficiently improved to warrant the opening of all its wards. The hospital was incorporated

by Act of Parliament, which received the Royal assent in April, 1838.

The hospital is remarkable from the fact that it has possessed, since January, 1792, a fund for the endowment of a ward for the reception of persons afflicted with cancer. The fund was provided by S. Whitbread, and it has enabled the officers of the hospital carefully to check the remedies which have been recommended at various times for the cure of this deadly affection.

An attempt to teach students of the hospital was made as early as 1796, when a laboratory was fitted up in order that chemical lectures might be given, but for many subsequent years the students of the Middlesex Hospital attended the Windmill Street School of Medicine. The founders of the London University (afterwards University College), in 1828, endeavoured to attach the Middlesex Hospital to the new institution, but with a curious blindness to their own interests, the governing body of the hospital rejected every overture, and the University authorities therefore established the North London or University College Hospital. The Windmill Street School was dissolved about the same time, in consequence of Sir Charles Bell's appointment as Clinical Professor in the new University, and it became imperative to establish a school in the Middlesex Hospital. This was accordingly done in 1835. The most notable members of the staff have been Dr. Peter Mere Latham, Sir Henry Hallford, who was called Dr. Henry Vaughan, during the time (1793-1800) he served the hospital, Sir Thomas Watson, Mr. John Shaw, Sir Charles Bell, and perhaps the most highly gifted of all, whose loss we still mourn, Mr. John Whitaker Hulke.

UNIVERSITY COLLEGE AND ITS HOSPITAL.

Enormous strides were made in the social and political state of England during the first thirty years of the present century, and University College marks the advance made by education about this time. The idea of establishing a liberal university in London which should be free from the trammels of the older universities and teaching bodies was long a favourite idea of the poet Thomas Campbell. This idea became a reality owing to the energy of Mr. (afterwards Sir) Isaac Lyon Goldsmid and of Lord Brougham. Active measures to found an establishment under the title of the London University were taken in April, 1825, and in 1826 seven acres of freehold ground were obtained between Upper Gower Street and the New Road. Mr. Wilkins, R.A., immediately proceeded to the erection of the present buildings upon the site thus acquired, and professorial work commenced in them in the autumn of 1828. The institution, commenced as a private enterprise, was strong enough to apply for and obtain a charter of incorporation granted in November, 1838. Some opposition, however, having arisen, and King's College having become incorporated in the meantime, a separate charter was granted to a new body, whose business it was to examine and not to teach, and to this body was applied the title of the London University, which it still retains, the older teaching establishment in Gower Street being subsequently known as University College.

The medical faculty was at first well represented by excellent teachers, but internal dissensions drove them out, and for the first few years of its existence the faculty passed through most troublous times. Matters mended in course of years, and the teaching staff as well as the medical staff attached to the hospital has been an unusually strong one for many years past; the Quains, Sharpey, and Ellis being perhaps the foremost teachers; whilst Liston, Syme, Parkes, Jenner, and Reynolds represent the most celebrated of the hospital staff.

The Hospital commenced as the University Dispensary at No. 4, George Street, Buxton Square, on September 8th, 1825, a week after the authorities of the Middlesex Hospital had disavowed any arrangement or connection with the University. The staff consisted of Anthony Todd Thomson, James Quain, David Davis, Samuel Cooper, Richard Quain, the surgeon, and J. Hogg. Steps were immediately taken to found a hospital fully equipped for clinical teaching, and funds were so rapidly obtained for this purpose that the centre block adapted to contain 150 beds was commenced in 1833 and opened in the following year. The hospital staff consisted at its opening of Dr. Edinboro,

Dr. Thomson, and Dr. Carswell as physicians; Dr. Davis as obstetric physician; Sam. Cooper, Robert Liston, and Richard Quain as surgeons. The hospital was at this time called the North London Hospital, it then became the University College Hospital, and in 1861 both names were combined. New buildings were added from time to time, and in the year 1869 the hospital authorities improved the nursing arrangements by entering into an arrangement with the All Saints' Home for a supply of trained nurses, who were to be under the supervision of the Lady Superior of the Home, though they were subject to the control of the matron of the hospital. The hospital was fitted up, at the instance of Dr. Tilbury Fox, the physician to the Skin Department, with an elaborate system of medicated baths, which under certain conditions are available for other than patients of the hospital.

KING'S COLLEGE AND ITS HOSPITAL.

The origin of King's College, London, was a meeting held at the Freemasons' Tavern on June 21st, 1828, when the Duke of Wellington took the chair. It was decided that a college for general education should be founded in the metropolis, in which, while the various branches of literature and science are made the subjects of instruction, it was to be an essential part of the system to imbue the minds of youth with a knowledge of the doctrines and duties of Christianity as inculcated by the United Church of England and Ireland. The College, being under the immediate patronage of George IV, was to be called "King's College." Letters patent were granted to it on August 14th, 1829, and the new institution was placed under the care of various high officials and Church dignitaries. A secession of the extreme Protestant party took place in 1829, and it was not until October 8th, 1831, that the College was formally opened. The Chairs in the Medical Department were then occupied by J. H. Green, Herbert Mayo, Dr. Bisset Hawkins, Dr. Frank Hawkins, Richard Partridge, and Dr. R. Ferguson. The connection of the College with the Established Church has always been maintained, and has lately been reaffirmed by the Council, though students of almost all religions and sects have been pupils. King's College has done good service to the medical profession by constantly advocating the necessity of a sound preliminary education for medical students.

King's College Hospital arose naturally out of the requirements of the medical department of the College, and it was established chiefly by the exertions of Dr. R. B. Todd, the Professor of General Anatomy and Physiology. It is situated at some little distance from the College and was, until recently, surrounded by slums of the worst description. It was opened in 1839, upon the site of the old St. Clement Danes Workhouse in Portugal Street, at the back of Lincoln's Inn Fields, and unless report lies more than usual a part of the buildings of the hospital were erected upon a burial ground in which upwards of 5,500 bodies had been interred within the previous twenty-five years. One hundred and twenty beds were utilized in 1839, but in 1840 it was found that the accommodation was insufficient both for the patients and the students. The present building was erected and opened upon the old site in 1861. The nursing was in the hands of a voluntary nursing sisterhood from 1836 to 1885, but since that time the nursing arrangements have been entirely in the hands of the Hospital Committee.

King's College School and Hospital have had a long array of glorious names upon its staff. Sir Thomas Watson delivered his classical lectures upon medicine in the school soon after it was opened, Dr. Paris occupied the Chair of Materia Medica, Sir William Ferguson was Surgeon to the charity for many years, Sir William Bowman was Ophthalmic Surgeon, Ferriar gained his laurels here, Sir Joseph Lister perfected his system and made the hospital known throughout the world as the home of antiseptic surgery.

THE ROYAL FREE HOSPITAL AND THE LONDON SCHOOL OF MEDICINE FOR WOMEN

The Royal Free Hospital, situated in Gray's Inn Road, was founded as a protest against the system then in vogue at the large hospitals of requiring a letter of recommendation before a sick pauper could obtain admission. The hospital owes its foundation to the following accident:

In the winter of 1827, Mr. Marsden, a practitioner living at

the top of Holborn Hill, found a girl of 18 dying of disease and starvation at midnight upon the steps of St. Andrew's Church, in Holborn. He conveyed her in a hackney coach to three or four of the large hospitals, but at each she was refused admission because the necessary letter of recommendation was wanting, and eventually he was obliged to take her to a lodging, where she died unrecognised two days later. This scandal produced so great an effect upon Marsden's mind that he determined to found a hospital into which disease and destitution should be the sole passports for admission. Friends came forward, and in 1828 a house was opened in Greville Street, Hatton Garden, under the name of the London General Institution for the Gratuitous Cure of Malignant Disease. The sympathies of Mr. (afterwards Sir) Robert Peel—the Home Secretary—were enlisted, and through him the patronage of King George IV was obtained, and the Duke of Gloucester became the first President.

The reputation of the hospital was greatly increased by the liberal policy pursued by its managers during the great epidemics of cholera in 1832-33, 34, 1848, and 1864. The doors of the hospital were thrown open to all persons afflicted with the disease, at a time when the other hospitals closed theirs on the ground that the admission of cholera patients would endanger the safety of those already in the hospital.

A fund was started in the spring of 1843 to build a larger hospital. A site was obtained in the Gray's Inn Road, which had been formerly in the occupation of the Light Horse Volunteers, and the nucleus of the present building was erected. The hospital is still supported by spontaneous contributions from charitable people. It is recorded that the subscription box at the gate has more than once been found to contain banknotes of great value contributed by persons who desired that their donations should be absolutely without a name.

No school was attached to the hospital for many years; but in 1877 an agreement was entered into by which the medical staff of the hospital were permitted to give clinical instruction to students attending the London School of Medicine for Women in Handel Street, Brunswick Square.

THE LABORATORIES OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND ROYAL COLLEGE OF SURGEONS OF ENGLAND.

In 1886 a Joint Committee was appointed by the two Royal Colleges to report on the subject of the disposal of an unoccupied plot of land adjoining the Examination Hall on the Embankment. The Committee reported that it was desirable to utilise the vacant ground for scientific purposes under the control and management of the two Colleges, and that the "scientific purposes" should be in the first place the investigation and exposition of such branches of science connected with medicine and surgery as the two Colleges should from time to time determine. It was then agreed to erect a building suitable for the purposes named above, together with a Lecture Theatre capable of accommodating 400 persons. Plans were prepared by Mr. Stephen Salter, the architect of the Examination Hall, and a contract was entered into with the builders for £24,067. Modifications having been subsequently introduced, the original estimate was reduced by £909 3s. 9d. In 1889 regulations were drawn up for the management of the laboratories by the Joint Committee of Management appointed by the two Colleges. In 1890 Dr. German Sims Woodhead was appointed Director, and the Committee were able to report that the laboratories were in working order. Permission to work in the laboratories is not restricted to those whose names are on the *Medical Register*. Application for this permission must be made to the Director in the first instance; the application is then submitted by him to the Committee at their next meeting. The publication of the results of work done in the laboratories is under the control of the Committee of Management. Ever since the completion of the building the workrooms have been fully occupied, and much good original work has been accomplished. The laboratories and workrooms are thoroughly fitted up with the most modern appliances for bacteriological and other kinds of research. A note of the work done in

each year is published in the Report of the Secretary of the Royal College of Surgeons, which may be found in the *Calendar* of that institution. No separate publication has been issued by the Laboratories Committee, but the results of the work done have been for the most part communicated by the various workers to the medical journals.

DONARIA OF MEDICAL INTEREST

IN THE OPPENHEIMER COLLECTION OF ETRUSCAN AND ROMAN ANTIQUITIES.

FROM NOTES BY DR. LUIGI SAMBON, Rome.

THE custom of making offerings to the gods is found among the ancients from the earliest times of which we have any record. Such gifts were called *donaria* by the Romans, and were generally offered as tokens of gratitude but often they were intended to induce the deity to grant some favour.

Anything could be offered to the gods—land, buildings, cattle, fruit, war implements, tools of trade, jewellery, cast-off clothes. Repairs of the temple and embellishments of the sanctuary by paintings and decorations were considered most suitable *donaria*. Some *donaria*, such as materials for the religious ceremonies, statues of gods and money were given indifferently to all deities; other offerings were given only to some special divinity; thus the temple of Artemis Brauronia was filled with women's clothing.

In the temples of healing gods were gathered mostly instruments of surgery, pharmaceutical appliances, painted tablets representing miraculous healings, and great numbers of images of various parts of the human frame shaped in metal, stone and terra-cotta.

Some of these temples were magnificent buildings richly decorated, but often they were mere shrines at the source of some hot spring or mineral water where great numbers of patients flocked from far and near. Here they would bathe or else only drink the water. The priests regulated the use of the waters and prescribed further for each patient. The patient always threw an offering into the water before leaving, a bronze astragalus, a silver cup, a coin or some terra-cotta model of a limb, which was left bubbling in the water while the sufferer, dragged himself off muttering a prayer. A representation of a woman throwing her *donarium* into a tank of healing water appears in a painting on a Greek vase in the Louvre. More often the *donaria* were hung about the walls of the temple and clustered round the statues of the gods, as we learn from the inventories engraved on marble which have been found among the ruins of the old temples.

When the temples or the tanks of healing waters were overcrowded with valueless *donaria*, the priests used to remove them to grottoes or wells dug in the neighbourhood or they buried them enclosed in large wooden boxes or simply in deep furrows from which they are now occasionally disinterred.

Magnificent offerings such as cups of valuable metal with votive inscriptions have occasionally been found. The old temples contained many objects of gold and silver, but few remain because *donaria* of precious metals were, after a time, melted into ingots, and disposed of by the priests according to special regulations peculiar to each temple.

Amongst the votive deposits are nearly always found coins of every epoch and place, from the shapeless pieces of bronze called *as rude* which was the primitive money of Italy and preceded the coined metal or *as signatum*, to coins of the empire. Such coins give most interesting information as to the approximate dates of the period in which the sanctuary where they are found was frequented, and perhaps of how far its fame was spread. The coins were sometimes attached by means of wax to the hands of the images worshipped. Many bear countermarks very likely to prevent their returning into use, others *graffito* inscriptions such as "sacred to Apollo."

Surgical instruments were offered by patients or surgeons often as a thanksgiving for a successful operation. Erostratus offered to Apollo in the temple of Delphus a forceps of lead to show how little he approved of the extraction of teeth which were not loose enough to be pulled out by the fingers.

Among the many surgical instruments and appliances found in all parts of the Roman Empire more than a hundred different ones are known, which are certainly not inferior to those of the present day. The old Roman instruments were entirely of metal, mostly of bronze and iron; some were beautifully shaped and richly inlaid with silver.

Large quantities of pottery are usually found, mostly broken into fragments; there are cups and vessels of every form and description, but generally of the coarsest kind. Even this pottery can give a certain idea of the epoch at which the sanctuary was frequented. Sometimes the cups are pierced with a hole by which they were hung up as a votive offering after they had been used, but generally they were thrown into the water. We are told gravely in a Greek inscription from Epidauros of a boy who had been carrying his master's favourite cup, and had gone to sleep by the roadside, to wake up and find the cup broken in pieces. He was in despair, when a passer-by remarked that only Aesclepius, the healing god of Epidauros, could mend the crock. This the god is recorded to have done, to the delight not only of the boy but also of his master, who, when he heard of the incident presented the cup to the temple.

Among the pottery I have found invalid medicine cups and feeding bottles for infants (*gutti*). Many of these are ingeniously fashioned in the shape of the female breast, some offer curious shapes of animals. I have found some which have a woman suckling her infant worked in relief on their surface evidently indicating their use, but what positively confirms these *gutti* to be feeding bottles is that they have been found by Mr. E. Toulouze, Dr. Allaire and myself in the tombs of children who died during the period of lactation. Here they had been deposited by mothers sometimes together with a rattling toy, as the most suitable furniture for the tiny grave. They replaced the dishes of various foods which were placed in the tombs of grown up people.

These old feeding bottles are so constructed that no flies or dust can reach their contents. The milk was generally introduced by inverting the bottle and pouring it through an open tube ascending within from the middle of the base almost to the apex, which also prevented its escape when the bottle was placed again on its base. The child obtained

Fig. 1.—Feeding bottle.

nourishment by sucking through a spout on the side of the article. On the opposite side is a small round handle. In my collection is a tiny feeding bottle of lead which had probably been made to be offered as a thanksgiving for successful feeding by artificial means.

Amongst the pottery of votive offering are often found vessels of very minute dimensions, which certainly could not have been of any practical use, some being hardly an inch high; this toy-like pottery had evidently been brought to the shrine as a symbolical offering, instead of the usual vessels which now filled up the tanks. A great number were found in Civita Lavina by Lord Savile; they have also been found in tombs.

The most interesting and least known donaria are certainly those representing limbs and viscera of the human body or

images of patients showing evident marks of disease upon them. There is hardly any part of the body which has not been shaped out of the clay. It was a common custom amongst patients to offer an image of a limb or organ which was diseased.

Fig. 2.—Section to show construction of feeding bottle.

Innumerable are the heads found in each votive deposit. They are of every epoch and size; some few are of bearded men, a large number of youths and children, but the great majority is of women of every age. Mostly the whole head is represented, but sometimes only one side of it is shaped, the other being replaced by a flat surface. The most archaic are solid, the later ones are hollow and generally have a square or round hole behind by which they might be suspended. All these heads of different epochs from the most archaic to those of the latest periods offer an interesting study on the hairdressing and adornment. The hairdressing in return giving a certain information as to the period and locality to which they belong. In a general way those wearing diadems belong to the earliest period, the others veiled in many ways to the latest. Their age varies from the fifth century B.C. to the second A.D.

These heads or half heads were most commonly consecrated as representing the part of the body affected by disease, but many represented the grateful patient himself, and some, which are modelled by the hand instead of being cast, are perhaps portraits of the same. Of the many hundreds I have examined none present signs of disease; only one head modelled which was found in a votive deposit consecrated to Minerva Medica in Rome, suggests alopecia areata, but the locks which are missing, chiefly at the back of the head, may have fallen off accidentally, the tresses or ringlets having, as was not infrequent, been separately modelled, and attached afterwards to the head. None of these heads offer

Fig. 3.—Ear from Palestrina.

any special attributes which might prove them to be images

of gods. Often only a part of the face or head is represented, generally the fronto-labial region, on a square or rounded plaque.

Fig. 4.—Eye found at Vel.

Ears and eyes are found singly in large numbers and vary immensely in shape and size. In the National Museum of Rome are two terra-cottas representing the labial region. In my own collection is a very neat representation of a tongue with its ligaments (glosso-epiglott. med. and glosso-

Fig. 5.—Dissected trunk found near Rome. epiglott. later.), on each side of its base are two rounded prominences, probably representing the tonsils. Numerous trunks of both sexes and all sizes are found.

In many of them we observe large openings, either limited to the chest, or extending to the pubes and exposing the internal organs. The openings present the *technique* of our days. Sometimes only the pelvis is represented; one in the Florence Museum shows the uterus through an abdominal section. Often the internal organs of one or both cavities are represented on distinct plaques. The anatomy of these sections is generally very poor, but the workmanship varies immensely from one terra-cotta to another, and while some of them offer a totally mistaken and conventional term or grouping, others are formed with extraordinary skill. These terra-cottas had no aim at scientific accuracy; they were modelled in vast quantities by any wayside potter and sold for a trifling sum on the road to the temples, mostly to ignorant peasants. A careful study of human anatomy was therefore not needed and the majority of potters who shaped these donaria probably contented themselves with a short examination of the butcher's shop.

Very different must have been the anatomical knowledge of the medical men of those days, because we know that human anatomy was eagerly studied on the bodies of prisoners and slaves. Celsus, in his work which is the masterpiece of Roman medical literature, repeatedly emphasises that there can be no rational medicine without a complete knowledge of human anatomy. Erasistratus had dissected the human body at Alexandria and Herophilus had even vivisected criminals under sentence of death.

From the vast quantities of anatomical terra-cottas bought and dedicated by patients of all classes, we can surmise that gross anatomy was thus far better known to the general public than it is at the present day.

Arms, legs, hands and feet are found very abundantly and sometimes single fingers. The hands are generally represented as opened in the attitude of worship. A left hand in Dr. Charles's collection in Rome presents nodulated tumours over the first phalanx of the ring and little fingers; another one in the same collection has two fingers flexed at the metacarpo-phalangeal joint, probably the result of broken extensor tendons. One in my collection offers over-extended fingers as occurs from injury of one of the main nerves of the arm supplying the flexors and skin.

The feet are sometimes clad in sandals, the sole being shaped in the clay and the straps only painted. A foot in Professor Charles's collection stands on a very high sole probably to improve the gait in ankylosis.

Hearts (Fig. 6) with their auricles very prominently

Fig. 6.—Heart.

shaped, kidneys, uteri, ovaries and coils of intestines are often found singly. In the National Museum of Rome is a rough model of the larynx and trachea (Fig. 7).

Female breasts are extremely common.

Male genitals are also found in great number, always with long foreskin completely covering the glans penis; many of these terra-cottas suggest phimosis from venereal disease.

Reproductions of the vulva are often found, sometimes offering the characteristics of childhood, at other times those of puberty.

Fig. 7.—Larynx and Trachea.

Uteri are found in great numbers, some generally of the size of the normal viscus with a smooth surface; others are larger in size and offer a wrinkled surface and patulous cervix as after delivery (Fig. 8). They were offered as pro-

Fig. 8.—Uterus after delivery

pitulatory gifts to ensure an easy labour or given by way of thanksgiving after safe delivery, or after recovery from difficult labour or disease.

Some of these uteri have on one side the appendages attached (Fig. 9). I have found that the left ovary and tube is far

Fig. 9.—Ovaro-salpingitis with adhesions.

more commonly represented, proving even in those days a marked prevalence of disease of the appendages of the left side.

Some uteri present a double opening at the os (Fig. 10); they

Fig. 10.—Uterus septate.

are undoubtedly representations of uteri septi. I have found no other malformation of the womb represented by these tern-cottas, such as uterus bicornis, although they are, com-

paratively far more frequent. But this is not surprising because uterus septus is easily diagnosed during life by a simple manual examination if the septum extends as far as the os, while other malformations are difficult to detect except in post-mortem examinations. As the terra-cottas representing uteri septi are rather frequent although the malformation is rare, I believe that the idea of twin pregnancy was closely connected with it, and thus the double opening may be considered, in most cases, as a conventional form indicating it.

(To be concluded.)

A REPORT ON THE MILK SUPPLY OF LONDON BY A SPECIAL ANALYTICAL AND BIOLOGICAL COMMISSION.

II.

In carrying out our investigation into the quality of the milk supplied to London, we have, in the first instance, caused samples to be taken in poor districts by reliable persons who made the purchases in such a manner as to ensure that each sample represented what was being supplied at the time to the ordinary customers of the shops selected. The quantity asked for in each instance was small, and no information was given as to the object of the purchase. In this manner, during the month of June, thirty samples were taken in the poorer districts of Westminster, Marylebone, Lambeth, and Battersea. The report which we have received upon these samples shows results of a striking kind. Of the 30 samples only 6 were reported as being of "genuine composition," 16 were found to be more or less sophisticated by the addition of water or the abstraction of fat, or both, even where the calculations of the results were based on the lowest limits of quality which it is possible to adopt, 7 were unquestionably sophisticated upon the basis of a somewhat higher but perfectly fair standard of quality in regard to fat; and 1, while otherwise of genuine composition and fair quality, had been tampered with by the admixture of a boric acid preparation, 9 of the otherwise sophisticated samples having also been found to contain boric acid.

There are different ways of reporting the results of analyses of this kind, and the variations necessarily existing in the composition of a natural product like milk create some amount of difficulty; but the composition of genuine cow's milk is well known to vary within such limits that, leaving out of consideration the peculiar fluids that single animals may be made to yield or that may be extracted from abnormal ones, the assertion of important sophistication in any given case is a fairly easy matter with the aid of a full and accurate analysis. If deficiency of fat is found, the amount of that deficiency may be calculated on the assumption that a genuine milk should contain not less than 3 per cent. of fat as determined by modern and accurate methods of analysis, or on the higher and fairer standard of 3.5 per cent. The deficiency may be stated as a percentage of "original fat abstracted," but inasmuch as deficiency of fat is now generally brought about by the admixture of "separated milk"—which contains practically no fat—with a milk of genuine composition, it is convenient to regard milks sophisticated in respect of fat deficiency as made up of "milk devoid of fat" and of a milk of genuine composition.

It is a well-known fact that, under existing conditions, public analysts to whom samples of milk are officially submitted under the Adulteration Acts are compelled to base any condemnatory reports or certificates upon very low

limits of quality. It must be admitted that 3 per cent. of fat is as low an amount as can possibly be allowed in an article to which the term "milk"—meaning thereby cow's milk—can still be legitimately applied. It is true that certain animals may be made to produce almost any liquid from their udders by improper or inadequate feeding and by bad management and unhealthy surroundings; but because this is the case it is absurd to contend, as it is sometimes contended, that a purchaser who asks for milk is entitled only to get the very worst product that can be extracted from the udder of an abnormal cow. It has been proved by thousands of analyses that, especially at this time of year, a purchaser may justly expect to get at least 3.5 per cent. of fat in the milk with which he is supplied. If he does not get it, and the "milk" which he does get is, as we have already pointed out, "standardised" by the admixture of separated milk until the amount of fat present is just on the limit that will "pass" the public analyst, the fraud is as obvious as any for which the law provides punishment far more drastic than that which is ever visited upon the milk swindler.

Some idea of the nature of this form of milk fraud and of the profits attending it may be gained by a consideration of the fact that a sample such as No. 1 in the table which we print on the next page, reported as containing 8 per cent. of milk devoid of fat, or as having had 8 per cent. of the original fat abstracted—which amounts to the same thing—would be reported as being deficient to the extent of 20 per cent. of the original fat, or as containing 20 per cent. of milk devoid of fat, upon the 3.5 standard. The magnitude of the frauds revealed by the results shown in the table is made more striking by observing what the figures mean when applied to "bulk," that is, to considerable quantities; 25 per cent. of added water means that in 100 gallons of mixture foisted on the public there are 25 gallons of water—perhaps in itself filthy and dangerous—and 77 gallons of a fluid defined as "milk of the poorest quality." A glaring case is furnished by a sample of a preparation 100 gallons of which would contain 26 gallons of separated milk having no fat, 21 gallons of water, and 53 gallons of "milk of the poorest quality." The artificial colouring and the dosing with boric acid preparations, whereby stale milk is made to pass as fresh, afford additional illustrations of the manner in which so many milk purveyors conduct their trade, and are points which, with those previously commented upon, may well be pondered over by those who consider that adulteration and sophistication are only "forms of trade competition," and that no Acts of Parliament are required to keep certain traders, shopkeepers, and trading companies from committing the meanest and most atrocious frauds.

REPORT UPON THE ANALYSIS OF THIRTY SAMPLES OF MILK.

By CHARLES E. CASSAL, F.I.C.

Public Analyst for Kensington, St. George Hanover Square, etc.

I CERTIFY that I have analysed 30 samples of milk, numbered from 1 to 30, on behalf of the British Medical Association Special Commission. From a consideration of the results of my analyses I have arrived at the understated opinions concerning the composition of the samples (see Table). It is to be noted that 3 per cent. of fat is the lowest amount which should be present in a sample to which the term "milk" can still justifiably be applied, and that a purchaser ought fairly to receive not less than 3.5 per cent. of fat in an article sold to him as milk. A sample of milk of the Aylesbury Dairy Company, purchased in the ordinary way shows 4.2 per cent. of fat. In those cases where the fat found was less than 3.5 per cent. but not below 3 per cent., the percentage of fat deficiency on the 3.5 standard is shown. Inasmuch as deficiency of fat is generally brought about by the admixture of separated milk, which contains practically no fat, with a milk of genuine composition, it is convenient to regard milks deficient in fat as made up of "milk devoid of fat" and not of "genuine" composition. In those cases where the amount of fat found was below 3 per cent. the calculations have been made on the lowest or 3 per cent. limit, a fact which is indicated by the genuine milk present being reported as "milk of genuine composition but of the poorest quality."

(To be continued.)

REPORTS

ON

THE NURSING AND ADMINISTRATION
OF WORKHOUSES AND
INFIRMARIES.

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

II.—ST. GEORGE HANOVER SQUARE.

THOUGH it retains its old name, this workhouse now serves the parishes of Westminster and Chelsea as well as that of Hanover Square, and has incorporated into itself the old Chelsea House called "Little Chelsea." It has accommodation for about 2,000 inmates; the infirmary is adjacent, and communicated by a covered corridor with the chapel which thus serves the two buildings.

CLASSIFICATION

is almost impossible, as the quarters are crowded; on the

female side smaller day rooms and better airing courts enable the authorities to keep the older and better-class women from consorting in the daytime with the worthless and ill-conditioned, but the crowded state of the dormitories must go far to nullify the good effect of better classification by day; the master seemed to feel the hopelessness of his task under present conditions.

THE BUILDING

is another instance of the style known as "patched," and still there is a cry for more room. The house is built in blocks, of which the upper floors are connected by bridges; the old part consists of four blocks, and the newer part is in the same style. There are single bedrooms for the married couples, with a cheerful day room common to all; here we saw the men playing games, and the women were mostly occupied with needlework. Near the entrance is the probationers' ward, where the new comer is detained until classified by the medical officer.

THE OLD AND INFIRM

are located in separate blocks; there were 60 in the male wards and 153 in the female. For these there are two nurses, with pauper help, and there is one nurse at night, also assisted by paupers. We were glad to learn from the master that the guardians contemplate increasing the staff, for, though the inmates are not sick, they require in many cases as much assistance as children, and it is useless to expect attendance from the pauper helps. There is no doubt that the cunning old hands levy contributions from the hapless before rendering service. The system is hopelessly wrong; it is not the fault of the officers, who have far more work on their hands than they can properly execute, and adequate supervision is impossible with the present proportion of administrators to administrated. And in the meantime those who know the conditions are aware that the practice of setting one pauper to tend and control another is responsible for much petty tyranny, and even absolute cruelty, which can never be exposed and punished.

ON VISITING THE DORMITORIES

we found them in possession of the cleaners, who were endeavouring to eradicate the vermin by burning out the nests and eggs in the interstices of the bedsteads. The old frame of the bedsteads must be favourable to the propagation of these pests, and it seemed to us that until they were discarded for others of a more modern make, which will take to pieces and wash in chloride of lime, the wards will still be infested, especially as the old building is also likely to harbour vermin in the joints of the floors and woodwork.

The wall surface is of painted brick. Some of the ventilators consist of a square piece cut out of the ceiling, hanging from cords, which are presumably attached to some frame-work in the roof. They looked somewhat dangerous, as there was no means of ascertaining the state of the cords. In other wards the ventilation was supplied by the upper sash of the window.

THE NURSERY

is a cheerful and pleasant room, but it is badly situated, since the children must mix with the able-bodied in the airing court on to which it opens. Girls of 12 or 14 years of age are detained here when from any cause they are in the workhouse, and this arrangement ought not to be tolerated for a moment. Two trained nurses are in charge of this department, and the mothers come to suckle their infants; otherwise they only visit the nursery on visiting days. We were sorry to see the tube feeding bottle in use, and would recommend that the old-fashioned boat-shaped bottle should be substituted for it. Another desirable improvement is the provision of a metal lined receptacle for the soiled napkins which are waiting removal to the laundry.

THE LECTURE

have a small self-contained department of 8 beds for each sex, under the charge of an attendant. The padded room is very good. Here are detained the patients waiting removal, and also those whose noisy habits render them unfit to be with the sane. We were surprised to notice that neither here nor in the epileptic wards were any special beds provided;

the narrow beds with unprotected sides seemed hardly safe for such patients.

THE SANITARY AND LAVATORY ARRANGEMENTS were undergoing alterations. On the female side there are fixed basins outside the dormitories with hot and cold supply; on the male side the fixed basins are out of doors, with the result, as the master said, that the old men do not wash in cold weather, or they make use of the chamber utensil in the dormitory. The old women, as we were informed by an inmate, preferred to make this use of the chamber vessel instead of that for which it is intended; we can understand that among this large number of paupers, many coming from the very lowest class, there will be some who, if left to themselves, will show every trace of the state of savagery out of which they have come, but we do not see the necessity of the workhouse lowering itself to their level.

The sanitary arrangements are weak, baths few and not well placed; that for the infants and children appeared to us to be too deep, but already the engineers were at work turning the place upside down, so that it was not easy to gain a clear idea of details.

THE LAUNDRY

is of ancient construction, small and ill-found; when we consider that from 16,000 to 17,000 pieces pass through the laundry in a week we wonder that the task can be accomplished at all. The mangles are turned by hand, the washing machine is small, there is only one wringer, the drying closets are small, there is no callender, indeed no machinery to speak of. The small room for counting the soiled linen is dark and ill-ventilated; the folding and ironing are carried on in a recessed room off the drying room. For all these defects there is but one remedy—to build a new laundry; and we trust that the guardians will put that matter in hand without loss of time.

DEATHS UNDER ANÆSTHETICS.

CHLOROFORM.

OUR Berlin Correspondent writes, under date July 14th:—Two deaths under chloroform, one following close upon the other, have occurred in Berlin. The inquest in both cases showed the presence of a heart defect, which should not have passed unnoticed by the operator, and which should, it was held, have caused him to abstain from using chloroform. It remains to be seen whether the verdict of the inquest will be the last one spoken in this matter.

ROYAL COLLEGE OF SURGEONS.

A QUARTERLY Council was held at the College on July 11th, Mr. CHRISTOPHER HEATH (President) in the chair.

The PRESIDENT reported the result of the election of members of the Council at a meeting of the Fellows on July 4th. He further stated that 681 Fellows had voted, and of these 621 sent their votes through the post, while 60 voted in person, the votes of 2 of these Fellows being, however, invalid. Mr. Davies-Colley received 29 plumpers, Mr. Alfred Cooper 19, and Mr. William Anderson 17.

The newly-elected members of Council were introduced, and, having made the customary declaration, took their seats on the Council.

The minutes of the last meeting were then read and confirmed.

On the recommendation of the Museum Committee it was resolved to purchase the skeleton of a *Dinornis maximus* from the Canterbury Museum, Christchurch, New Zealand, for £70, in accordance with the valuation of Dr. Woodward, of the Natural History Museum, and to employ Mr. Barlow to articulate the skeleton at a cost not exceeding £15.

A donation by Miss Greenhill, of several volumes in MS. of a lexicon of Greek medical terms, compiled by the late Dr. Greenhill, of Hastings, was accepted with the best thanks of the Council.

The PRESIDENT reported that a half-yearly meeting of the Fellows had been held on July 4th, at which 45 Fellows, including 14 members of the Council, had attended, but that as

no notices of motion had been given for the meeting, no discussion of any kind took place.

The following statement of the attendance of the members of the Council during the past year was announced:

ELEVEN MEETINGS OF THE COUNCIL IN THE YEAR.

Name.	Meetings Attended.	Name	Meetings Attended.
Mr T. Spencer Wells, Bart.	9	Mr. Alfred Willett (Vice Presi-	11
Mr Jonathan Hutchinson	9	dent)	11
Mr. William Cadge	10	Mr. T. Pickering Pick	10
Mr. Thomas Bryant	11	Mr. H. G. Howse	11
Mr. Thomas Smith	11	Mr. John Langton	11
Mr. J. W. Huike (died after 7th	7	Mr. W. Mitchell Banks	9
meeting)	7	Mr. W. Livingston	11
Mr. Christopher Heath (Presi-	11	Mr. T. R. Jessop	9
dent)	11	Mr. F. Howard Marsh	11
Sir William Mac Cormac	10	Mr. J. Tweedy	11
Mr. A. E. Durham (died after 9th	3	Mr. Henry Morris	11
meeting)	3	Mr. A. W. Mayo Robson	9
Mr. N. C. Macdonald	11	Mr. J. Hardie	6
Mr. Oliver Pemberton	9		
Mr. Reginald Harrison (Vice-	11		
President)	11		

A letter was read from Mr. H. R. Hope-Pinker, stating that he would be pleased to make a replica of his marble bust of the late Sir William Savory, Bart.

It was announced that the signatures of the Secretary of State and Lord Chancellor to the new By-laws had been obtained.

A petition from the London School of Medicine for Women, asking the Council to admit women to the examination for the diploma of Membership, was referred to the Committee of Management.

Mr. Heath was elected President of the College for the ensuing year, and Messrs. Harrison and Pick as Vice-Presidents.

The next meeting of the Council will be held on Monday, July 29th.

A LEGISLATIVE JOKE.

WE have received from a correspondent at Cape Colony a copy of a Bill to amend the Pharmacy Act, 1891, published in the *Cape Times* of June 5th, 1895.

Our correspondent draws attention to the fact that the editor of the *Cape Times* calls the Bill "a Legislative joke," but our correspondent thinks that readers may be interested in the manner in which medical legislation is carried on, or attempted, in the Colony.

The Bill, we understand, is suggested as being in the public interest, but the fees prescribed thereby would apparently be rather the other way. Certainly the fees relating to surgical operations are somewhat vaguely indicated.

The Bill proposes that no fees shall be recovered in a court of law unless they are in accordance with the subjoined tariff. A second clause would enact that every physician when rendering an account shall specify all items for "medicine," and shall not be entitled to payment for such "medicines" of any sum "beyond that which, according to law, the chemist and druggist can lawfully charge."

SCHEDULE.—TARIFF OF CHARGES FOR PHYSICIANS.

	£	s.	d.
Examination of a person and certificate	...	1	0
Each visit within the limits of the town:			
Daytime	...	0	5
At night	...	0	10
Each visit beyond such limits with the exception of the fees allowed by this tariff:			
If travelling at his own cost, per hour	...	0	10
If travelling at the cost of the patient	...	0	7
Amusement	...	3	0
A certificate of cause of death (not including the view-			
ing of the body)	...	0	10
A surgical operation, including the loss of a limb	...	10	0
A usual surgical operation	...	0	10

The reading of the Bill was received with roars of laughter. The Bill was set down for second reading on the 19th instant.

PRESENTATION.—Mr. Hugh Lewis Hughes, L.R.C.P. and S., of Dowlais, has been presented with a timepiece and candelabra, bearing the inscription: "Presented to Dr. Hughes by the members of the Women's Ambulance Class, Dowlais, June 14th, 1895." This is the seventh occasion on which the members of the local St. John Ambulance classes have shown their appreciation of his services as surgeon-instructor.

BRITISH MEDICAL ASSOCIATION. SUBSCRIPTIONS FOR 1895

Subscriptions to the Association for 1895 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office Orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, JULY 20TH, 1895.

THE WASTE OF EXPERIENCE.

THE three Hunterian Lectures that Mr. T. Holmes has just delivered at St. George's Hospital are welcome for many reasons and profitable in many ways. In the first place they give us a mass of valuable cases full of instruction—the whole six years' wealth of work, unsifted, unselected, all as they happened, good and bad together. Let any student who does not know the unique value of unselected cases make a careful abstract of these lectures, and then he will find that unselected cases teach us twice as much as selected cases can ever teach.

In the next place these lectures show us how we may check the terrible waste of experience that goes on in every hospital throughout the world. These 110 cases of abdominal section were useless to the profession till Mr. Holmes put them together and published them. Each case at the time taught something to those who watched it from first to last, but each new case effaced the lessons taught by its predecessors; and thus the whole mass of cases, utterly useless outside the walls of the hospital, became, even within those walls, an ill-defined bundle of memories. Each case was exciting enough at the time, and floated a few days on the broad stream of hospital talk, but they left behind them no clear rules to guide the student when he came to be in practice.

Now here is a way to make a real and honourable privilege out of that most barren of all compliments—the position of consulting physician or consulting surgeon to a hospital. You must have, first, a loyal and united staff; you must have also a consulting physician or surgeon still keen for the advancement of his art, still in touch with "the surgical miracles of our time," still possessed of exact judgment as to the value of the new methods and the old. To him the notes of every case in the hospital should lie open; it should be his duty to survey the whole work, past and present, of the hospital, and from time to time he should take some great theme in medicine or surgery and should set forth the whole experience of the hospital during many years in that particular subject, publishing every single case and making use of every scrap of knowledge that could be got out of the hospital casebooks. Such work as this would be of the very highest value, but at present, in every hospital, the precious materials for it are running to waste.

In the third place, these lectures are full of good advice and sound encouragement. Mr. Holmes is not one of those

who overpraise the past. Speaking of abdominal section for acute obstruction, for example, intussusception or internal strangulation, he says: "All the operations which I have myself performed, or which my colleagues performed during the period of my service here, were, I believe, unsuccessful." He delights to count the lives saved at St. George's Hospital during the last six years: 4 recoveries after the operation for internal strangulation, 3 after gastro-jejunostomy, 4 after perforation of gastric or duodenal ulcer, and so on; he has the happiness of recording a total of 42 recoveries out of the 110 cases; and of the operation for perforated gastric ulcer he says: "This really seems to me the most wonderful of all the surgical miracles of our time." He is careful to praise the admirable work of Mayo Robson, Lockwood, Morse, Reginald Jowers, and others, besides that of his colleagues, Dent, Penrose, and Lee Dickinson. His tone throughout is one of delighted and thankful recognition of the advance all along the line.

And in this respect he gives a very wise answer to those unhappy and distracting questions, with a personal sting in them, as to the duty of the physician towards the surgeon in these cases. Surely, in such emergencies, the physician and the surgeon should act together "for the mutual society, help, and comfort that the one ought to have of the other." But some physicians prefer the old paths; the case belongs to them; they will watch it; if they think the surgeon is wanted, then they will send for him. Let us hear Mr. Holmes's decision: "These cases should be still, I think, as before, physician's patients; but the house-physician might be instructed to send for both physician and surgeon immediately on the patient's admission, so that the consultation can be held without any further loss of time, and the operation performed, if necessary, on the spot." This advice is pure gold both for the patient and for the surgeon. How can the surgeon hope to study these cases aright unless he sees them at once? What can he learn if he be suddenly called to the bedside several days after the admission of the patient? The patient's condition is masked by drugs; the physician, the house-physician, the patient all give him their own "history of the case." He may operate, and he may be successful, but if he is ever to be a master of abdominal surgery he must see each case at once on its admission and study it for himself.

These considerations of Mr. Holmes's lectures have not touched the actual stuff of which they are woven. That does not matter; there are the lectures, to be read diligently again and again by everybody who is or desires to be a good surgeon.

LITTLE WARS AND THE SMALL-BORE RIFLE.

FOR a nation which, like ourselves, is frequently involved in small frontier wars and engaged with enemies whose nervous development is apparently less exalted than that of the European, a question which has been raised more than once before—in the Zulu War and in the Sudan campaign for example—in connection with the new small-bore rifle, assumes very serious importance. The question is, Will these new rifles stop a rush, a charge of savages or of fanatical dervishes? It is all very well to be able to hit a man at 2,000 yards range, but it is of greater moment to know that when hit at 100 or 200 yards distance, a man

cannot still continue his onward rush so as to come within striking limits.

We publish this week a very interesting series of cases of gunshot injury by the Lee-Metford rifle as observed in the recent Chitral expedition. These cases, as briefly reported by Surgeon-Lieutenant Gould, indicate very clearly an effect resulting in actual warfare, which, as we have hinted, has been more or less anticipated by military surgeons and others, not only from theoretical generalisations, but from experiments on the cadaver and from the observation of gunshot injuries caused by the same weapon under circumstances of accident or homicide. The remarkable penetrating powers of this rifle, the peculiar drilling effect of its projectile, and the curious absence of shock and extensive smashing of bones in those hit is well illustrated in these reports.

Of the 20 cases recorded by Mr. Gould we find all ending in recovery, notwithstanding the fact that the conditions of treatment were necessarily rude, and that in more than one instance the anatomical structures involved were of such importance that their injury, under most ordinary conditions, would have entailed the severest consequences. Possibly some allowance must be made for the fact that all the patients were native tribesmen, and drawn from a race who are notoriously tolerant of surgical and operative interference. It would be interesting to know whether a similar series of European cases would yield equally satisfactory results from the surgical point of view. It is unfortunate that information is wanting as to the precise range at which these men were hit, but the presumption is that it was well within a thousand yards. Even in the absence of exact details on this point these cases constitute an important contribution to the literature of the effects of the modern small-bore rifles and their bullets; the series further endorse the so-called humanitarian claim on behalf of these weapons; but, as we have said, they tend to confirm the very serious doubts felt from a fighting point of view as to whether they will stop a rush.

The facts at present collected are insufficient to justify any want of confidence in this weapon for fighting at close quarters against fanatics, but, at the same time, they clearly indicate a possible disadvantage in its use, and further emphasise the need of close observation of all wounded, and the casualties caused by these small-bore rifles at all ranges by medical officers. Their interpretation cannot fail to be of value to those whose duty it is to advise the War Department upon ordnance questions.

THE LEPROSY QUESTION.

We have already called attention to a recent resolution of the Government of India in reference to the leprosy question in that country, and have noted that the conclusions of the Leprosy Commissioners have been to a great extent accepted by the authorities, and that there is no intention of adopting any general measures for the compulsory segregation of all the lepers of India. It is satisfactory to observe that one of the conclusions at which the Commissioners arrive has been abundantly confirmed by the final statistics of the late census—namely, that the number of lepers in India has been greatly overstated, that the available figures showed either a decrease in the number of persons affected,

or at any rate good evidence that the progress of the disease had been checked, and that consequently the alleged spread of leprosy could not be regarded in the light of a national danger. The revised figures at the census of 1881 give 126,361 lepers, of whom 31,069 were females. The recommendation of the Commission that lepers should be prevented from engaging in certain trades and occupations has been adopted in so far as the prohibition may apply to municipalities, and to the larger fairs and gatherings. The general recommendations, directed against mendicant lepers leaving their homes and crowding into large centres of population are also in a great measure accepted, and the Government propose that vagrant lepers in municipalities be dealt with in the same way as vagrant lunatics under the Act of 1858.

The Government also endorse the recommendation that competent medical authority be consulted before any action with regard to lepers be taken. To carry out these regulations asylums on the model of the Madoonga institution in Bombay are to be erected and maintained at the cost of the municipalities and local boards; and it is recommended that the necessary local legislative enactments be on the lines of the Bengal Leprosy Bill which has been lately brought forward. The suggestion of the Commission in reference to the establishment of leper farms or colonies has not been adopted by the Government, or at any rate its consideration has been postponed.

In contrast to the authoritative opinion of the Indian Leprosy Commissioners, now practically endorsed by the Government and its sanitary advisers, that leprosy is not a contagious disease, we may point to the notice, in the last number of the *BRITISH MEDICAL JOURNAL*, of the report recently presented by a Special Commission appointed by the Government of the Cape of Good Hope. A diametrically opposite view is therein taken, and a system of general isolation strongly recommended. A definite increase of leprosy in South Africa appears to be well established, and the belief in medical quarters that the disease has increased by inoculation from person to person is as strongly maintained as ever.

The facts and arguments in this report are ably stated, and its appearance at this time forcibly shows the wide difference of opinion still existing among competent authorities with regard to the etiology of leprosy and its practical management.

SURGEON-GENERAL WILLIAM CAMPBELL MACLEAN, M.D., C.B., has been selected for appointment as an Honorary Surgeon to the Queen in the room of the late Inspector-General J. H. Orr, M.D., C.B.

The Council of the Royal College of Surgeons of England has appointed a committee to receive a deputation of the Members regarding the proposed amended charter on July 26th, at 3 P.M.

H.R.H. the Princess of Wales will present certificates to the third and fourth thousand nurses of the Royal National Pension Fund for Nurses, at Marlborough House, on Friday, July 26th, at 3 P.M.

The Electoral Anti-Vivisection League issues the following as a leaflet: "Vote for no one who will not promise to insist on the total prohibition of vivisection—that means, experimenting on living animals—which always leads to experimenting on patients in hospitals."

OUTBREAK OF TYPHUS FEVER AT LEITH.

THE medical officer on July 16th reported to the Leith Town Council that there had been an outbreak of typhus fever, but it was being kept well in hand; there had been twelve cases, some doubtful cases, and two deaths. On the whole, it was a mild outbreak. All the cases had sprung from one source.

AN ENGLISH EVICTION.

SINCE the publication of an article in the *BRITISH MEDICAL JOURNAL* under the above heading, we have received a communication from Sir William Worsley's solicitor, taking exception to the version of the case given by the *Leeds Mercury* (as being influenced by political bias), and justifying the action taken on behalf of Sir William Worsley. We are pleased to give the same publicity to this statement as we did to the story as told by the *Leeds Mercury*.

LOCAL ENTERTAINMENT AND EXCURSION COMMITTEE.

IN consequence of the unavoidable absence of Dr. R. Boxall, it is requested that all future communications referring to the entertainments and excursions be addressed to Dr. Symons Eccles, 28, Hertford Street, Mayfair, W.

MIDWIVES REGISTRATION.

DR. R. R. RENTOUL AND DR. HUGH WOODS have issued a circular summoning a meeting of practitioners opposed to the formation of an inferior order of midwifery practitioners at the St. Martin's Town Hall, Charing Cross Road, on Monday, July 29th, at 9 p.m. The circular states that it is of the utmost importance that members should attend, as those opposing "their views are using every means to defeat the motion of Mr. L. Tait and Mr. C. Campbell."

IRISH DISPENSARY DOCTORS' LOCUM TENENS.

A CASE of much importance has just been decided by Mr. Justice Johnston at the Cavan assizes. The Kingscourt Dispensary Committee allowed the medical officer, Dr. Dempsey, fourteen days' leave, and agreed to pay his *locum tenens*, Dr. McEvoy. The guardians, however, refused to pay the sum of £3 3s. a week, as agreed upon, on the ground that the Dispensary Committee had no right to make the appointment. In the court below Dr. McEvoy's action for his salary was dismissed, but Mr. Justice Johnston reversed that decision and gave a decree for the full amount claimed.

THE LATE PROFESSOR TRAUBE OF BERLIN.

A BEAR of Ludwig Traube, the eminent Berlin clinician, who died nineteen years ago, has been placed in the garden of the Charité Hospital, Berlin. Traube's two daughters and many distinguished medical men, among them Virchow and Leyden, were present at the ceremony of unveiling. Professor B. Fraenkel spoke of Traube as the unforgotten teacher, whose admirable exactitude of observation and immense pathologico-physiological knowledge which enabled him to judge the value of clinical symptoms, had remained an ever-present example to his pupils.

LONDON SCHOOL OF MEDICINE FOR WOMEN.

THE Duchess of Portland on July 9th distributed the prizes to the students of this school. After an address by the Dean, Mrs. E. Garrett Anderson, M.D., the Duchess of Portland presented the prizes, and said that there was a large field for medical women in Eastern countries, and also in hospitals for women and children in our own country. Mr. Arthur T. Norton, the President, in laying the balance-sheet before the meeting, stated that there was a balance in

favour of the school last year of £100. He especially appealed for assistance to the building fund. Before the meeting closed an address of thanks was presented to Sir James Stansfeld, from the Council of the school, for the assistance he had rendered in the establishment and encouragement of the institution, and generally in the cultivation of female medical education.

BIRTHS TO ORDER.

IN India it is customary to entrust the duty of registering births and deaths in outlying country districts to natives, who are generally as ignorant of reading and writing as they are of English. Their memories, unperplexed by knowledge, are, however, retentive, and these registration officers may frequently be seen tramping, in companies of four or five together, into the city, to hand over verbally to the collector the data regarding the births and deaths in their several localities. Suspecting once that the records were carelessly kept in a certain village, a collector reported that the ratio of births was below the average, and suggested to the registrar that his returns could bear improvement. "Ah, it's more births the sahib wants," was the inner thought, and, with Indian amiability and actuated by the desire to say the thing which pleased, the registrar's returns showed at once a remarkable increase in the number of births. All the babies were duly registered by name, and there was evidence that the village was prospering as population increased. Presently the vaccination officer began to ask why it was that he had no increase of vaccinations, and why these numerous babies were not brought to him. This natural question led to an inquiry, and to the discovery that the children registered so accurately had been born only in the ardent imagination of the registrar, and had been produced in his earnest desire to please the *sahib*.

ENDOWMENT OF SCIENCE IN JAPAN.

DR. KITASATO is not only the most brilliant scientific investigator in Japan, but one of the most original biologists of the present day of any nation. He worked for many years with Koch at Berlin; and last year, when the plague was devastating Hong Kong, he and Dr. Aoyama discovered the bacterial cause of the plague, and were thereby instrumental in arresting its ravages. He has been extremely successful in carrying out the antitoxin treatment of diphtheria, and out of 34 cases treated by him 31 have recovered. He is at present engaged in carrying out a series of experiments on leprosy with the most satisfactory results. If it is a fact that Dr. Kitasato is on the road to discovering not only the cause, but the cure, of leprosy, he will confer an immense benefit on a long-suffering section of the human race. Japan has always been celebrated for generously acknowledging the services of her men of genius in art and literature, and it is gratifying to learn that Dr. Kitasato's discoveries are looked upon as contributing to the national glory, and that the Government has unanimously voted him a sum of money to be devoted to the laboratory superintended by him.

THE COST OF TYPHOID FEVER.

DR. MUNRO, medical officer of health for the county of Renfrew, has published the approximate cost of an epidemic of typhoid fever which occurred in Mid-Renfrewshire. There were 829 cases, out of which 74 were fatal. The average cost of hospital treatment was about £8 15s., on which figure Dr. Munro puts the average cost of treatment all round at £5 per head, a figure which seems certainly well within the mark. From data to which he has had access he puts the amount of wages lost to the patients at £3,391. The cost of funerals is taken at £5, and the capital value of a human life at Farr's low figure of £100 per head. The total pecuniary cost of the epidemic to the community of Mid-Renfrewshire was accordingly £21,490, or just over £25 for each

case. These figures are all calculated on the very lowest scale, and no doubt were in fact exceeded. If local authorities could realise such figures they would see that, quite apart from questions of sentiment or moral duty, no expenditure could yield a better return on the investment than that which is bestowed on the provision of pure water supplies and the establishment of isolation hospitals and adequate means of disinfection.

BRAZILIAN QUARANTINE.

We are glad to learn that there is a prospect of some diminution and improvement in the severe quarantine restrictions which have been hitherto maintained by the Government of Brazil. Perhaps the most unwarrantable of these has been the maintenance of a single quarantine station for a country having such an immense seaboard as Brazil possesses, an arrangement which often involved a sea voyage of a thousand miles when a vessel was ordered into quarantine. It is now announced that at a sanitary conference held at Rio de Janeiro between the Brazilian Government and representatives of Great Britain, Germany, Italy, and of the French and Argentine Republics, four fresh quarantine stations are to be maintained; and there is also to be some relaxation of the undue and exceptional severity of some of the quarantine restrictions. One or two special hospitals are to be constructed, so that the sick may be removed from the ships. Suspected ships—that is those on which there is at the time no sickness—will be allowed to unship passengers and cargo under certain circumstances, provided there is no personal intercourse with the shore. Mail bags are to be landed from any vessel, whether there is disease on board or not; and it will then rest with the Brazilian authorities to deal with the letters, etc., as they think fit. Ships which are healthy, but which happen to have sailed from infected or suspected ports, will only be subject to "observation" instead of quarantine—whatever this may mean. In this way another country is making some useful advance in the direction of British freedom from restriction; and we can only hope that it will before long be made evident to all nations that it is the abolition of restrictions that has always gone hand in hand with those sanitary improvements afloat and ashore which in the end show how useless restrictions are. We cannot refer to quarantine without expressing regret that, owing to the recent dissolution of Parliament, we shall be compelled for another year to maintain our useless quarantine hulks, which are forced upon us by the effete and antiquated Quarantine Act of 1825, and the Orders made under that statute.

CHOLERA IN THE EAST.

SUSPECTED cholera cases have been reported at the quarantine camp of El Tor, and the Quarantine Board has declared that the place will be regarded as infected until the end of the pilgrim season. The epidemic in Asia Minor, which was first reported from Tarsus, so far from having terminated, has spread recently, being apparently carried by refugees, and at the meeting of the Comité Consultatif d'Hygiène, M. Monod observed that the ease with which the capital of the vilayet has been infected, in spite of all the efforts of the civil and military authorities, indicates once more what value is to be assigned from the prophylactic point of view to the sanitary cordons and interminable land quarantines to which the Turkish Government seems to attach importance which increases in proportion as facts accumulate to prove its inefficacy.

THE EDINBURGH ROYAL SOCIETY.

THE last meeting of the session was held on July 15th; Sir Douglas MacLagan (President) in the chair. The Macdougall-Brisbane Prize for the biennial period 1892-94 was presented to Professor James Walker (University College, Dundee) for

his work on physical chemistry. Professor T. R. Fraser made a further communication on antivenene, and on the production of immunity against the venom of serpents. Subcutaneous injection had always been used—a method attended with inconvenience. But the venom was nearly inert in the stomach, though a certain amount of resistance to subsequent lethal doses was obtained. Some of the results obtained might afford an explanation of the immunity enjoyed by certain snake charmers in India, and these results might also explain the immunity possessed by venomous serpents themselves.

CHELSEA HOSPITAL FOR WOMEN.

AN unfortunate event has broken the seeming smoothness of the course on which the Chelsea Hospital for Women had lately embarked. No details have as yet been made public, but a grave question has been raised concerning the performance of a serious operation, in regard to which, it is alleged, the new rules of the hospital as to consultations were not complied with, and which was carried out in opposition to the adverse advice of one of the operator's colleagues. The Chairman of the Board, it is said, has summarily called for the resignation of the medical officer in question, which he declines to tender. It is also stated that the medical officer involved in the matter is one whom the Board of Management had itself taken the responsibility of placing on the staff of the hospital, in disregard of the recommendations of its medical committee of selection, a proceeding on the part of the Board on which we commented at the time. It is of importance to him, as well as to the profession and the public, that the whole matter, which is being much talked of, should be publicly cleared up.

DIPHTHERIA AND SCHOOLS.

THE Mayor of Wrexham (a town in which there appears to have been some prevalence of diphtheria of late) should undertake a course of reading in the reports of the Local Government Board, and pay especial attention to those which refer to outbreaks of diphtheria; had he done so earlier, he would scarcely have ventured to characterise a suggestion of school closure as nonsense, or have committed himself for the whole of futurity to a policy of non-closure. He contended, and rightly, that even if excluded from school the children would continue to meet, but he left out of account the difference of conditions between meeting in the school atmosphere and out of doors, a difference which has repeatedly been found to decide the question of epidemic or no epidemic. The report of the council's proceedings in the *Wrexham Advertiser* concludes with an intimation that this question was ultimately referred to the Public Health Committee, so perhaps the medical officer of health will carry his point after all, although he has failed to convince the mayor.

THE "PHARMACEUTICAL JOURNAL."

WE heartily congratulate the Pharmaceutical Society upon the new departure which has taken place in the extension and the improvement of the *Pharmaceutical Journal*. Its matter could hardly be improved. This new departure dates from the celebration of the twenty-fifth year of Dr. B. H. Paul's editorship. All those who have watched the progress of scientific pharmacy and of pharmaceutical administration, will be ready to testify to the skill, moderation, sound judgment, and tact, which have never failed to characterise the conduct of the *Pharmaceutical Journal* during that period. The attitude of a journal which is at once the mouthpiece, the leader, and the controlling influence in a great Association is a work requiring the combination of many qualities. The editor needs discretion, devotion, progressive instincts, and the faculty of initiation; his journal must never be stagnant or dead; he must never disregard

the material interests of his constituents, and he would be very unwise if he were, in seeking to attain a temporary popularity, to allow them to assume a predominant influence, whether by pure terrorism or unreasoning alarms seeking to cloak themselves under whatever disguises, and so to drown the voice of conscience and those greater interests of the profession which are identical with the public interests. In the claim for new privileges he must always calmly distinguish the part which should be assigned to duties. It is his part to seek out modest merit, and to give every capacity its opportunity, and to the humblest unit of many thousands his place on the platform and his equal voice where intrinsic merit should speak for him. Dr. Paul has passed through the period when organisation requires extension and purification of these unmannerly elements which must at first exist in every newly constituted body. He has been able to surmount all these difficulties. The *Pharmaceutical Journal* stands now in a foremost place among professional and technical journals of Europe, and it is no small credit to him that he has attained for it that position without ever sacrificing all those lower elements of popularity which sometimes purchase cheap success at the expense of higher and more enduring good. Everyone will wish a further career of extended popularity to a journal so ably edited and conducted in so excellent a spirit.

OFFICIAL HONOURS AND UNOFFICIAL GIFTS.

Mr. J. J. FRANCIS, Q.C., and Mr. F. H. May were both active members of the Permanent Committee of the Sanitary Board of Hong Kong, to whose efforts were due the successful measures taken to combat the plague when it was devastating Hong Kong last year. Mr. Francis was chairman of the Committee, and claims to have been its brain and motive power. In recognition of the services of these two gentlemen the Government have made Mr. May C.M.G., but have presented Mr. Francis (the Chairman) with a silver inkstand. The gift was returned, with a letter, to Lord Ripon. Public sympathy is with Mr. Francis, and the *Hong Kong Weekly Press* says: "It was generally understood that Mr. Francis should at least be made a C.M.G., and to ask him to accept a paltry inkstand, while conferring a C.M.G.-ship upon his colleague on the Permanent Committee, Mr. F. H. May, can only be construed as a marked and intentional insult." The reason is said to be that Mr. Francis is not an official, and in Crown colonies public services are not recognised by public honours if performed by those outside the charmed circle. It is not only in Crown colonies that this is the case; but we trust that services such as those rendered by Mr. Francis to the cause of public health and at a period of such crisis and alarm as that of the recent plague will be adequately acknowledged by the Government.

COUNTRY PRACTICE IN SOUTH AFRICA.

Is the July number of the *Phonographic Record of Clinical Teaching and Medical Science*? Mr. Herbert Caiger gives his experience of country practice in South Africa. His work extends over an area for twenty miles on every side of a small village of 200 souls in the Orange Free State. The fees are regulated by a tariff fixed by the State, £5 being allowed for an ordinary midwifery case, and all time spent in travelling is paid for at the rate of ten shillings per hour. The Dutch farmers have large families, twelve or sixteen children being quite common, so that midwifery is an important branch of practice. Mr. Caiger tells of one doctor who had fifteen cases on hand at once. The Dutchman does not resort to the doctor until he is compelled; but he has great faith in a bottle of physic, and describes a good doctor as one who gives good medicine. In spite of the comparative isolation, of the fact that the doctor is sometimes mistaken for a superior kind of chemist, and notwithstanding

Issued by the Society of Medical Phonographers. Price 6d. London: Mr. L. Pittman and Sons.

the warning that an up-country doctor may find life so dull that he is tempted to take either to morphine or whisky, Mr. Caiger says that a man who will rough it and take things as he finds them may make a comfortable living, and have a fair amount of leisure time in up-country practice at the Cape. He points out, however, that owing to trade depression and the influx of medical men from the old country, the openings are not so numerous as they were.

DEMONSTRATION OF THE PREPARATION OF ANTI-TOXIC SERUMS.

THE Director of the British Institute of Preventive Medicine, Dr. M. Armand Ruffer, will demonstrate at the Institute's farm at Sudbury, near Harrow, on July 31st and August 2nd, at 4.30 P.M., the mode of the preparation of therapeutic serum for various diseases, including diphtheria, tetanus, erysipelas, etc. The demonstrations will be open to all members of the Association, but Dr. Ruffer will be greatly obliged if members wishing to be present will kindly give notice of their intention to the Director, 101, Great Russell Street, on or before July 30th.

Train from Euston to Sudbury	...	3.40 P.M.	Return trains from Sudbury at 5.31 and 6.11 P.M.
(Trains will meet the train at Sudbury.)			
Lecture	...	4.30 P.M.	
Tea	...	5 to 6 P.M.	

THE LONDON HOSPITALS AND THE APPROACHING ANNUAL MEETING.

At several of the hospitals in London the medical and surgical staff have announced their intention of offering special hospitality to provincial members of the Association. A large number of special invitations have been issued by the staff of St. Bartholomew's Hospital to a luncheon in the great hall of the hospital at 2 P.M. on Wednesday, July 31st. On Thursday afternoon a garden party will be given at the Hospital for Sick Children, Great Ormond Street, by Mr. John H. Morgan, surgeon to the hospital, and President of the Section of Diseases of Children. On Friday from 3 to 6 P.M., members of the Association are invited to visit Guy's Hospital. The staff will exhibit cases of interest, and afterwards tea will be provided.

THE SICK POOR IN WORKHOUSES: ST. GEORGE HANOVER SQUARE.

In consequence of the ugly rumours which have been current for some time past about the arrangements and management of this house, we sent a representative to visit and report on the matter. Any criticism of such an institution must, to be fair, take into account the fact that actual Boards of Guardians have to deal with structures which were erected when population was smaller, and the ideas of sanitation and even of common decency were very different to what they are now. Nor must we forget the difficulty of dealing with the London pauper, who often seems to be ignorant of the very rudiments of civilization. But neither consideration can justify the policy of "laissez faire," and the Guardians of the richest parish in London should look to it that such obvious defects as are pointed out in the report be remedied with all possible despatch. But the question is a wider one than the eradication of vermin from one particular house, or the construction of suitable laundries. When is some statesman going to introduce order into the chaos of our Poor-law administration? In all the great towns there should be classification of houses, the sick in one department, the infirm in another, the tramps in a third; the children separated from the adult, and sent to mix with other non-pauper children. In every country union there should be an equally careful classification of inmates. This is the great need of the day. Not until there is some adequate form of classification will there be any real hope for the diminution of pauperism. But when there is security that

the innocent child, the honest labourer past work, and the sick, will not be confounded with the idle and dissolute, housed under the same roof, subject to the same indiscriminating discipline, then the good sense of the people will not oppose such deterrent measures as shall really make the condition of the able-bodied pauper less eligible than that of the poorest wage labourer. As things now are, many Boards of Guardians, knowing that the house is no place for the decent man or woman, are apt to lean, if they are humane, to the out-relief which perpetuates the evil of pauperism. It is the absence of classification which gives weight to the cry for increased relief out of the house. Let the sentimentalists of to-day read the report of the Poor-law Commission of 1894, and see what comes of the abuse of out-relief; while wiser men study to remove evils which stimulate a demand to which it were ruinous to yield.

THE PROPOSED HUXLEY MEMORIAL.

SIR JOSEPH FAYRE presided on July 16th at a meeting in connection with the Huxley Memorial, which it is proposed to establish at Charing Cross Hospital Medical School. Mr. Waterhouse (Secretary of the movement) read a letter from the Duke of Saxe-Coburg, who was to have presided, and who wrote highly commending the scheme if it was not likely to interfere with obtaining additions to the funds for the maintenance of the hospital itself, an augmentation which was much needed. Among others who wrote were Surgeon-General Sir Guyer Hunter, Dr. Henry Huxley, Sir James Paget, the Hon. W. F. D. Smith, M.P., and Sir Savile Crossley. The Chairman said the great national memorial which would doubtless be erected to Professor Huxley's memory would not interfere with the memorial which they proposed to commemorate his connection with the school. He moved a resolution to the effect that it is desirable by means of a suitable memorial in connection with the school to permanently record the fact that the late Professor Huxley received his early scientific and the whole of his medical education within its walls, and thus to keep the example of his life and work constantly before succeeding generations of Charing Cross Hospital students. This was unanimously agreed to, and it was decided that the memorial should take the form of a Huxley scholarship and medal, to be awarded annually, and, if funds permitted, an annual public lecture dealing with recent advances in science and their bearing upon medicine.

VACCINATION DURING AN EPIDEMIC.

We feel bound to draw the attention of the profession to the case of Dr. E. C. Greenwood, who holds the appointment of Public Vaccinator under the Board of Guardians of the parish of St. Marylebone. This gentleman, it appears, had, when his parish was some time back threatened with a formidable outbreak of small-pox, much extra work thrown upon him—namely, that of visiting houses in the neighbourhood where the epidemic was prevalent, and vaccinating at their own homes all persons who might appear to require it as soon as they could be induced to submit to this protective operation. It must be evident that this was no easy duty, and that to render it effective would require considerable energy, and above everything else very great discretion. These qualities were, we believe, displayed to a very marked extent by Dr. Greenwood; and though, of course, it cannot be proved that the epidemic in question was cut short by his labour, it is impossible to doubt as to its having been very materially modified by his exertions. In any other department, valuable services such as these, rendered on an emergency when there was no time or opportunity to enter into a special contract in reference to the payment for them, would have been fairly or even liberally remunerated, without dispute or quibble. Such, however, has not been Dr. Greenwood's good fortune. He was in the first instance led to suppose that he would be paid not less

than 100 guineas for these extra and high-class services, but instead of this he received a cheque for one-quarter of that amount; this he returned as being quite inadequate. He has since been paid 50 guineas, or one-half the sum he considers he is entitled to claim. We should have expected the guardians of a wealthy West End parish to have treated any of the officials very differently from this, and are surprised to find that the Marylebone Board does not yet appear to have learnt that the prevention of such a disease as small-pox is even more to be desired than its cure, and that every case which actually occurs not only throws great and very serious responsibility on the sanitary authority of the district, but has the effect of paralysing the general business of the locality, and this at a pecuniary loss to the ratepayers which is impossible to calculate. It is in our opinion very questionable whether good judgment was displayed when the power of carrying out the Vaccination Acts now in force was entrusted to the Boards of Guardians throughout the county. Many of these Boards have since shown that they were quite unfit to undertake this important duty, and we regret to find that the guardians of St. Marylebone must now be placed in this list. Unless these Boards show greater ability in future, and better disposition to remunerate fairly for extraordinary services, the working of any vaccination laws must be placed in other and more efficient hands. The recent action of the Marylebone guardians will probably hasten this proposed and much-to-be-desired change.

HONOURS FOR THE CHITRAL EXPEDITION.

THE *London Gazette* of July 16th contains very long official despatches concerning the labours, the losses, and the successes of the Chitral Expedition. No particularly new points are developed, but the country will learn with satisfaction that Surgeon-Captain Whitechurch, who so gallantly attempted to save the life of Captain Baird during the sortie from the Chitral fort of March 3rd, has been granted the Victoria Cross by Her Majesty. Unhappily his heroic efforts were in vain, for though Dr. Whitechurch did all it was possible for man to do Captain Baird succumbed to his injuries after the fort had been regained. Dr. Whitechurch, observes the *Daily Chronicle*, is the fifteenth medical officer now living who has gained the coveted bronze medal and red ribbon "for bravery," the others being Surgeon-Major Hall, Assistant-Surgeon Sylvester, Surgeon-General Mount, Surgeon-General Home, Surgeon-Major Jee, Surgeon-General Reade, Surgeon-General Manley, Brigade Surgeon Temple, Surgeon-Lieutenant-Colonel Douglas, Brigade-Surgeon-Lieutenant-Colonel Reynolds, Surgeon-Lieutenant-Colonel Hartley, Surgeon-Major Crimmin, Surgeon-Captain Le Queene, and Surgeon-Major Lloyd. There are but 147 holders of the Victoria Cross for the army now surviving, and it is certainly remarkable that nearly 10 per cent. of them should be doctors to whom for so long the rank of combatant officers was denied. And now the very last to be conferred has also been won by a doctor. The Queen has further been pleased to nominate and appoint Surgeon-Major George Scott Robertson, C.S.I., Indian Medical Service, British Agent, Gilgit, to be Knight Commander of the Most Exalted Order of the Star of India.

THE METRIC SYSTEM.

It seems probable that what the arguments of men of science could not alone accomplish will be achieved owing to the pressure of competition in trade with foreign countries. A Select Committee of the House of Commons has again reported in favour of the legalisation of the metric system of weights and measures for trade purposes in this country, and has advised that the use of the system should be made compulsory after two years. Whatever there may be to be said for the duodecimal system on theoretical grounds, it is hopeless to expect that the majority of the nations of the world will adopt it; and for our own system, which is a

clumsy mixture of the decimal and the duodecimal, there is really nothing to be said. Lord Kelvin has called "our English system a wickedly brain-destroying piece of bondage," and there can be no doubt that it would be a great relief not only to men of science but to schoolboys if it were abolished. The medical profession is nearly interested in the change. The translation of a French or German prescription into British weights and measures is a tedious obstacle to free interchange, and in ninety-nine cases out of a hundred it cannot be achieved with convenience and absolute accuracy. The report of the Select Committee affords another argument for introducing the metric system into the revised *British Pharmacopœia* at least as an alternative, and for making the official solutions of decimal or percentage strengths. The arguments in favour of this change or addition were very fully set out in the last of the series of articles which we published recently on the revision of the *British Pharmacopœia*, and we anticipate with some confidence that they will prevail with the representative Committee which the General Medical Council has appointed to take charge of the work of revision.

CONGRATULATIONS TO PROFESSOR A. R. SIMPSON, OF EDINBURGH.

On July 4th, being the twenty-fifth anniversary of his appointment to the Chair of Midwifery in the University of Edinburgh, Professor A. Russell Simpson was entertained to dinner by his former and present assistants. During the evening a presentation of plate was made to Professor Simpson. Dr. J. Halliday Croom was in the chair, and a number of guests were present. On the following day the members of Professor Simpson's summer class also made him a presentation. As will be seen by our report of the meeting (at page 135) the members of the Edinburgh Obstetrical Society also entertained Professor Simpson as the guest of the evening at their dinner on July 10th.

ARISTOCRATIC BABY SHOWS.

London may be proud of seeing many of its ideas and its forms of enjoyment accepted finally by the upper ten thousand. Thus cycling, which was for years the joy of the masses, has now become the fashionable pleasure of the classes, and baby shows have now become the means of manifesting the maternal pride of aristocratic mammas. Truly there is no reason why little lords should not be appraised for their weight, size, number of teeth etc., in their infancy as well as the babes of Mrs. Jones, of Whitechapel, and Mrs. Brown, of Camden Town; but the competition for prizes should, we think, be national and be open to all proud mothers, whether of the masses or classes. It would be interesting to trace the subsequent history of prize babies and to ascertain if they furnished more distinguished men and women to the world than those who did not start so well in life. Mrs. Robert Crawshaw recently held at her house an aristocratic baby show, which was very largely attended. The first prize for weight and general excellence for babies under 1 year of age was awarded to Dermot Browne, son of Lord and Lady Castlerosse, who, though but 11 months old weighed 33½ lbs. The prize for weight and general excellence of development for babies over 1 year of age was awarded to Angela Mildred Baring, daughter of Lord and Lady Ashburton, who was 18 months old, weighed 28 lbs., and had 14 teeth. Information as to the feeding of these children would have been interesting.

THE LAW OF INFANTICIDE.

DR. JOHN GLANTER, in an admirable paper in the *Edinburgh Medical Journal* (July, 1905), calls attention once more to the exceedingly unsatisfactory state of the law on the subject of infanticide. It has long been recognised by writers on medico-legal subjects that the child is amply protected by our laws immediately after its birth, and to a less extent

whilst still in the uterus, but the law affords no protection whatever to it during the act of birth, and the killing of a child during birth is no crime unless the circumstances should be such as to bring the case within the definition of criminal abortion. All who have studied our records will know the extreme difficulty, we had almost said the utter impossibility, of obtaining a conviction against an unmarried girl for the murder of her illegitimate infant, no matter how overwhelming the evidence may be, the assumption in law being that the infant was born dead unless the contrary is made to appear by evidence. As a rule the prisoner is acquitted on the charge of murder or manslaughter, but convicted of another offence—namely, concealment of birth. No doubt this state of things has been passively acquiesced in because it has afforded a way of meting out some punishment to the girl, who is, however, often more aimed against than sinning. But it is eminently unsatisfactory, and savours somewhat of inconsistency that a prisoner should be convicted of concealing the birth of a child which has just been judicially declared to have never had existence. The Capital Punishment Commission made a very excellent suggestion on this subject some thirty years ago which has never become law, but which if adopted would go a very long way towards minimising the difficulty. Their report says: "We have arrived at the opinion that an Act should be passed making it an offence, punishable with penal servitude or imprisonment, at the discretion of the court, unlawfully and maliciously to inflict grievous bodily harm or serious injury upon a child during its birth or within seven days afterwards, in case such child has subsequently died. No proof that the child was completely born alive should be required. With respect to the offence of concealment of birth, we think that no person should be liable to be convicted of such an offence upon an indictment for murder, but should be tried upon a separate indictment. The accused should not be entitled to be acquitted in either of the above cases if it should be proved in the trial that the offence amounted to murder or manslaughter." Some such legislation as is indicated in these sentences is urgently needed, and we trust that in the new Parliament there will be found some who will take this subject up, and not rest until they have effected a change in our law upon the lines indicated.

THE MEDICAL HISTORY OF THE CRUSADES.

IN the *Revue Scientifique* of June 1st M. A. Corlieu gives a sketch of the medical history of the Crusades as far as it can be gathered from Joinville and other authorities. The condition of things may be summed up by paraphrasing the midshipman's description of the manners and customs of certain savages: there was no sanitation, and medicine (such of it as there was) was for the most part beastly. Albert, of Aix, relates that in the first crusade some champions of the Cross were bitten by snakes at Sidon and suffered from "tumours" (presumably oedema) and intolerable thirst. The treatment had perhaps best be given in the historian's own words. It was recommended *ut circumciseretur sine mora coiret cum muliere, cum viro mulier, et sic ab omni veneni tumore liberarentur utrique*. This method of neutralising the poison does not seem to have been particularly successful. The surgeons naturally acquired a very large experience in the treatment of wounds, incised, lacerated, and contused. Baldwin was severely wounded before Jerusalem, having received a spear thrust "through the thigh and the loins." He fell fainting from his horse, but the most skilful leeches were summoned "by whose art and skill the King and valiant athlete was enabled to recover from this deadly wound." Baldwin was also wounded in the foot before Antioch, and the surgical talent available was baffled by the injury to such a degree that it was proposed to kill a Saracen after wounding him in the same part, so as to learn the proper course to pursue. Baldwin, however, refused to allow this crude attempt at experimental surgery to be made. There seem to be no

medical records of the second crusade. In the third the French King Philippe Auguste and our own Cour de Lion suffered grievously from a disease, the symptomatology of which included extensive exfoliation of the skin, shedding of the nails, and loss of the hair. The disease is called *Arnoldia* by the chroniclers, and is variously conjectured to have been leprosy or syphilis. It could hardly have been leprosy, for both the royal sufferers recovered, Cour de Lion being killed eight years later at the siege of Chalus, and Philippe Auguste dying of quartan ague twenty-four years after Richard. Of the fourth crusade we have no medical details. In the fifth St. Louis of France was accompanied by his private physician Duden and other leeches; among them was a lady doctor or *phitienne* named Hernandis, who probably attended the Queen in her confinement, which took place at Damietta. The expedition suffered terribly from scurvy, typhus, and other pestilences. The part played by water in the diffusion of disease would seem to have been recognised, though the methods of water examination would hardly satisfy a modern chemist. A piece of white linen was dipped in the water to be tested and then dried; if there were any stains on the linen the water was condemned, but if not it was pronounced pure. The addition of four crushed almonds or beans was believed to make the water of the Nile safe for drinking. The method of disinfection adopted for the King's tent was to fumigate it with a mixture of amber, chick peas, or lupine, which were macerated in wine, and then placed on live charcoal. In the sixth crusade, which took place twenty-two years later, vast numbers, including St. Louis himself, fell victims to ignorance of the elements of sanitation. M. Corlieu gives some account of military surgery as practised in the Crusades, but in this part of his article we cannot help suspecting that he has followed the example of the author of a certain famous essay on "Chinese Metaphysics," by studying the *Cyruologia* of Theodoricus, the *Chirurgie de Maître Henri de Mondévillie*, and other mediæval writers on surgery, and "combining his information."

THE PATHOLOGIST TO THE LONDON ASYLUMS.

THE opportunities for the investigation of the pathology of nervous and mental disease in this country are so few in number, that the creation of the office of Pathologist to the London County Asylums has been hailed with much satisfaction. The duties of this office, to which Dr. F. W. Mott, Assistant-Physician to Charing Cross Hospital, has been appointed by the Asylums Committee of the London County Council, are to conduct researches into the pathology of insanity in all its bearings, and to make examinations of the pathological material at London County Asylums. He will be provided with a laboratory at the Claybury Asylum, and will have access to the wards of the asylums for the purposes of clinical study. The office thus affords many admirable opportunities, of which Dr. Mott may be expected to make excellent use, for advancing our knowledge of diseases of the nervous system. The salary attached to the appointment is £700 a year, and the pathologist will be required to devote the whole of his time to the duties of the office.

METHYLENE BLUE IN FILARIASIS.

DR. AUSTIN FLINT, in the *New York Medical Journal* of June 15th, 1895, advocates the use of methylene blue in chyluria and filariasis, basing his advocacy on his experience in one case of severe chyluria. In this case prior to treatment filariae were so abundant that "in each field of the microscope an average of ten embryonic filariae" were found; from the context we are led to infer that the field was that of an eighth objective. On March 5th two grains of methylene blue were given and repeated at intervals of four hours during the day. The same evening in four slides only two filariae were found, and these were sluggish and stained by the dye. The urine had become clear and of a characteristic greenish blue.

Treatment was discontinued. Blood examined on March 8th and 11th contained no filariae. On March 12th the urine had lost its blue colour, and had again become milky. During the night of March 13th filariae were found in the blood in great abundance; at the same time it was observed that the parasites showed a considerable amount of aniline staining, and that their movements were sluggish. On the following day methylene blue was again given; on the third day thereafter, on examining the blood, several dead and disintegrating filariae were found deeply stained. The urine had also cleared again. At the end of five days treatment was discontinued, and although the blood was frequently examined subsequently no filariae could be found, and the urine remained normal. We have had so many cures for chyluria and poisons for the filariae, which on subsequent trial have been found wanting, that we may be excused if we entertain a little scepticism about the virtues of methylene blue until we have further evidence. Unless the parent parasites are killed, even although the drug may for the time kill the embryos, which is still open to doubt, the patient is not much the better for the treatment; the embryos are sure to reappear in the blood. It is not the embryo that does the mischief—it is the parent worm; and even supposing that the parent worms are killed, it does not follow that the obstruction of the lymphatics which they gave rise to will disappear. The lesions they produce, and which are the proximate cause of filarial diseases, are permanent. Cases of chyluria are often met with in which the filariae which had given rise to the disease in the first instance had long disappeared; as a matter of fact, it is a rare thing to find filariae in ordinary elephantiasis. We fear there may have been some error in observation, or in the recording of this case, seeing that it is stated that no fewer than ten filariae were seen in one field of an eighth of an inch objective. It is difficult to understand how so many filariae could be packed into so small a space, or, if the blood vessels were so packed with parasites, what became of the blood corpuscles.

A NEW FRENCH TEMPERANCE MOVEMENT.

FOR some time past the thinking French mind has been growingly exercised on the urgent necessity for a resolute stand being made against the ravages of alcoholism. Consequent on the many recent outspoken medical counter-blows in France, *Le Soleil* and other leading journals have inveighed in the strongest language against specially the heavy premature mortality compared to which mortality from cholera is declared to be of "unparalleled benignity." In little less than half a century, since 1850, the consumption of alcohol has quadrupled in France, averaging in 1894 four litres per head. Dr. Legrain, Head Physician of Asylums in the department of the Seine, dwells on alcoholic heredity, and presents tabulated observations leading to these three conclusions: 1. Double parental alcoholism creates an irresistible tendency to drinking in the children. 2. Parental abstinence seems directly to transmit (very frequently fatally) epilepsy to the offspring. 3. The parental combination of abstinence drinking and epilepsy is a common cause of epilepsy in the children. Dr. Moreau de Tours gives cases of juvenile intoxication, stating that in the Lower Seine children drink large quantities of brandy on holidays. Dr. Roulinovitch, of St. Anne's Asylum, has begun to lecture on drunkenness and alcoholism to schools of teachers and pupils, and has heartily aided the recently-formed French Temperance Society, which seems to be based on the plan of the old English temperance societies, abstinence from spirits and strict moderation in wines, malt liquors, and cider.

NOTIFICATION OF INFECTIOUS DISEASES.—At a special meeting of the Perth local authority on July 9th, it was agreed, after a long discussion, by 14 votes to 5, to adopt the Infectious Diseases Notification Act.

PARLIAMENTARY BILLS COMMITTEE.

A MEETING of the Parliamentary Bills Committee was held at the offices of the Association, 49, Strand, W.C., on Tuesday, July 15th, 1895.

Present:

Mr. ERNEST HART in the Chair.

Dr. WARD COUSINS, President of Council.

Mr. BUTLIN, Treasurer.

Dr. S. H. AGAR (Henley-in-Arden).
Dr. A. G. BATHMAN (London).
Dr. T. BRIDGWATER (Harrow-on-the-Hill).
Dr. J. SPOTTISWOOD (Camden, Leeds).
Dr. W. F. CLEVELAND (London).
Dr. R. FILER (London).
Mr. E. H. GALTON (London).
Dr. BRUCE COPE (Bathwell).
Dr. W. GORDON (Exeter).
Mr. J. H. HEMMING (Kimbolton).
Professor V. HORSLEY (London).
Mr. EVAN JONES (Aberdare).
Mr. T. C. LANGDON (Winchester).
Dr. A. R. MANDY (East Rudham).
Dr. W. J. MICKLE (London).
Dr. J. W. MILLER (London).
Mr. JONES MORRIS (Portmadoc).
Dr. JAMES MURPHY (Sunderland).
Mr. C. H. WATTS PARKINSON (Wimborne Minster).
Dr. JAMES RITCHIE (Edinburgh).
Dr. G. E. SHUTTLEWORTH (Richmond Hill).
Dr. R. SOMERVILLE (Gala-shiels).
Mr. C. T. STREET (Newton-le-Willows).
Mr. W. THOMSON (Dublin).
Mr. T. JENNER VERRALL (Brighton).
Dr. S. WOODCOCK (Manchester).

The minutes of the last meeting were read and confirmed.

REGISTRATION OF MIDWIVES BILL.

The CHAIRMAN said that perhaps it would be for the convenience of the Committee if they took first the report of the Subcommittee to which the Medical Acts Amendment Bill was referred at the last meeting. Subsequent to the meeting he had asked the Subcommittee—consisting of Dr. R. W. Ballon (Gloucestershire Branch), Dr. Spottiswood (Yorkshire Branch), Mr. E. H. Galton (South-Eastern Branch), Professor Victor Horsley (Metropolitan Counties Branch), Mr. Evan Jones (South Wales and Monmouthshire Branch), and Dr. S. Woodcock (Lancashire and Cheshire Branch)—to consider the Midwives Registration Bill, and at the first meeting the Subcommittee decided to take the Midwives Registration Bill first, in view of it being already before the House of Lords, and they had prepared an amended Bill, which had been sent to the Branches for their opinion. The Bill, which was introduced into the House of Lords, had necessarily lapsed by the dissolution of Parliament and the resignation of the Government, so that there was in fact no Bill in existence and no Bill before the House of Parliament, and no one could tell when the matter would be again introduced into Parliament. He might add that when it seemed likely that the Bill might come on he provisionally communicated the draft Bill of the subcommittee to Lord Balfour, telling him that it was a report from a subcommittee. Lord Balfour wrote that he would consider the amended Bill carefully when Parliament adjourned. He wrote to Lord Balfour again to ask him to what extent he had been affected by the suggestions of the subcommittee, and what he had done in respect to the matter or proposed to do. Lord Balfour replied that in his present circumstances he could not in the near future undertake to write at length in regard to the proposals contained in the draft Bill, but when the pressure of the present emergency was over he would turn his attention to the subject. Lord Balfour had also sent two copies of his Bill as finally amended in the House of Lords. He proposed to have the Bill received from Lord Balfour and the Bill drafted by the subcommittee published in the BRITISH MEDICAL JOURNAL for the information of the Branches and the matter could then be discussed at a future meeting when a fresh Bill was before Parliament.

Dr. CAMERON (Leeds) said the Yorkshire Branch had considered the Bill, and their opinion was practically that they would not be satisfied with any Bill which recognised the

practice of midwives at all apart from medical practitioners. There must be something incorporated in the Medical Act which made it necessary for midwives attending cases being in touch with some qualified medical practitioner.

Dr. WOODCOCK (Manchester) said he should like to say, for the information of the Committee, that he had information that the Parliamentary Bills Committee had already exercised some influence over the minds of the Legislature. He had seen Lord Balfour, who had been supplied in a confidential manner with the draft Bill of the subcommittee, which gave him sufficient indication that the mind of the profession was turning to the question. Lord Balfour had said that he had seen that the profession was not blindly and obstinately opposed to the Bill, and he would be very glad to know what was the opinion of the British Medical Association, and what they proposed doing. At the annual meeting of the Lancashire and Cheshire Branch, the draft Bill was submitted, and it was felt that the matter affected so generally the whole of the profession that it would be unwise to take it into consideration; and it was decided to ask the Council of the Association to give directions for the Bill to be published in the BRITISH MEDICAL JOURNAL, so that the whole of the members of the Branches would have it before them, and have an opportunity to consider it.

Dr. SOMERVILLE (Gala-shiels) said the Committee ought to consider whether the mind of the profession was sufficiently made up on the subject for them to come to a decision about it just now. If the matter was postponed for a little while, he thought it would be well. There was now no Bill before Parliament, and Parliament was now dissolved. Lord Balfour of Burleigh was now a member of the Government, and he no doubt had other things to think about, and he had stated himself that he was not likely to bring in his Bill again. The Committee might consider whether on a subject about which the members of the Association were so much divided they should come to a decision on the matter. He thought, perhaps, it might be as well to postpone it.

Mr. JONES MORRIS (Portmadoc) said at a meeting of the Council of his Branch it was decided to postpone the consideration of the Bill. They would rather postpone the consideration of the Bill until the whole of the Branches had considered the Bill. Expressing his own views on the matter, having a very billy Poor-law appointment it could easily be imagined how very convenient it would be for him to have in the remote districts a woman who was properly qualified, who would be able to attend cases of natural labour, and if she found any difficulty in the case to at once send for a medical man. What was felt was that all those women who might, under the exigencies of circumstances, be called upon to attend women in their labours, should have some amount of education, and be qualified for that purpose, let it be training under a medical man or training in a hospital, and they should be registered in order that the district should know that that woman was one they could call in.

AFTER some further discussion it was proposed by the CHAIRMAN, seconded by Mr. Victor Horsley, and resolved:

That the report of the Subcommittee be received and entered on the minutes, but the Committee postpone further action seeing that Lord Balfour has withdrawn his Bill, and that there is at present no Bill before Parliament. At a future date the Committee will resume the discussion with the aid of the comments of the Branches upon the amended Bill drafted by the Subcommittee.

Dr. BRIDGWATER (Harrow-on-the-Hill) said, did not the Committee think it would be well to agree upon one point, that of the necessity of some change in the present system? They ought to go before the world with it prominently admitted that there was a necessity for a change, and then upon that would spring other steps. It was then proposed by Dr. BRIDGWATER, seconded by Dr. GALTON, and unanimously resolved:

That it is desirable that there should be a change in the present system in the practice of midwifery by unregulated, uneducated, and uneducated women.

The further consideration of the subject was postponed.

ANNUAL REPORT.

The CHAIRMAN said the next item on the agenda was the consideration of the annual report of the Committee which had been circulated.

It was proposed by Mr. JONES MORRIS, seconded by Dr. CLEVELAND, and resolved:

That the report of the Parliamentary Bills Committee be received and adopted, and laid before the next meeting of the Council.

MEDICAL ACTS AMENDMENT BILL.

The CHAIRMAN said he had received from the Lancashire and Cheshire Branch a rough draft Bill to amend and consolidate the Medical Acts, which probably the Committee would wish to be referred to the same Subcommittee to which the other amendments of the Medical Acts had been referred, who would consider it and take legal advice upon it if necessary.

FACTORY ACTS LEGISLATION.

The CHAIRMAN said they had not succeeded in getting all the amendments proposed inserted in the new Factories and Workshops Act. He had been working in co-operation with Dr. Holmes, Secretary of the Certifying Factory Surgeons Association, who had drawn up the following note, which showed the advantages which the new Bill conferred on certifying factory surgeons:—Under the present Factory Acts the duties of certifying surgeons are confined to the examination of children and young persons for certificate of fitness, and to reporting on accidents. In the latter case only have they the power to enter a mill to examine into the cause of an accident, and no power to enter the office to examine the Factory Register. Under the Factory Bill as passed by the House of Commons, Clause 18 clears up a doubtful point about accidents to be reported, and will thus in many districts increase the remuneration of certifying surgeons. Clause 20, causing a register of all accidents to be kept, will lead to many being reported to the certifying surgeon which have hitherto been neglected, thus again increasing his remuneration, but, what is more, it gives him the power to enter and examine the Factory Register, which hitherto he has not been entitled to do. Clauses 22 and 23 will give increased work, and, as all work is paid by fees, increased pay. Clause 29 ditto, and, for the first time, brings sickness due to the employment directly under the notice of certifying surgeons. Clause 46 provides for a limited amount of re-examination, and for the employment of certifying surgeon on special inquiries, the latter being an acknowledgment of their utility never made before. The clause also provides for the payment for services rendered under any special rules the Home Secretary may make. Hitherto the Home Secretary has had no such power to employ certifying surgeons. Undoubtedly Schedule 2 may affect injuriously a few certifying surgeons who are now getting special fees from enlightened employers for the periodical examination of hands employed in dangerous trades, yet the number affected is not likely to be large, as the Chairman only knew of one case, a correspondent to the BRITISH MEDICAL JOURNAL. None have made any complaint to the Association of Certifying Surgeons; had they done so the Association would have had a tangible ground on which to approach the Home Office for an increase of the schedule. A second correspondent writes to the BRITISH MEDICAL JOURNAL under a misapprehension as to the nature of Schedule 2.

GRIEVANCES OF ARMY MEDICAL OFFICERS.

The CHAIRMAN said the subcommittee to which the three cases of grievances of army medical officers were submitted at the last meeting had considered the merits of each case, and, without going into the precise reasons, the subcommittee recommended that the Committee should not interfere in two cases, and that in the third, the case of Surgeon-Major H. G. Gardner, they had reason to believe that he would be reinstated. If he should not be reinstated, the Committee should make further representations to the new Secretary of State for War that he be either reinstated or employed in a recruiting district.

CORK SOCIETIES MEDICAL OFFICERS' INDEMNITY FUND.

The following additional subscription is acknowledged by Dr. Denis Dempsey Donovan, King Street, Cork, Treasurer to this fund:

Yorkshire Branch, British Medical Association £ s. d.

MILKBORNE DISEASE:

AN APPEAL TO MEDICAL OFFICERS OF HEALTH.

MR. ERNEST HART is engaged on a general inquiry into milk-borne disease since 1881, in continuation of his paper of that year on the Influence of Milk in Spreading Zymotic Disease, and will be much obliged if those health officers who possess notes of outbreaks of disease traceable to the agency of milk will be good enough to furnish him with a brief statement of the facts, so far as known, in the shape of answers to the questions subjoined:

1. Date.
2. Locality.
3. Reporter.
4. Total number of cases.
5. Deaths.
6. Number of cases amongst drinkers of suspected milk.
7. Number of persons supplied by milkman.
8. Number of such families invaded.
9. Sanitary circumstances of farm or dairy from which milk was obtained.
10. Exciting cause of outbreak.
11. Circumstances implicating milk.
12. Facts showing special incidence of disease.
13. Reference to report.

Mr. Ernest Hart desires to express his thanks to the following medical officers of health for information which they have kindly furnished with reference to outbreaks of disease traced to the agency of milk: Dr. Ainley, of Halifax; Dr. John Brown, of Bacup; Dr. Gairdner, of Crieff; Dr. Paul Karkeek, of Torquay; and Dr. W. Brown, of Stapleton. Also to Mr. B. Davies, of Marylebone, for his paper of proposals in regard of the milk supply of London.

LITERARY NOTES.

In the *British Journal of Dental Science* of July 1st, Mr. H. W. Moore shows that the ancients knew a thing or two about dentistry. The Egyptians of course, as we know from Herodotus, made the teeth one of the innumerable allotments into which they parcelled out the human body for the benefit of professors of the healing art. Hippocrates recommended gold wire as the best fastening for loose teeth, and evidence that this method was used has been found in Greek tombs. Among the ordinances of the twelve tables of old Rome there is one forbidding the removal of gold fastenings from the teeth, which were to be burnt or buried with the body. Celsus speaks of scraping carious teeth, and from Martial we learn that the Roman ladies repaired imperfections in their dental apparatus by the help of art. The artificial teeth which they used were composed of bone and ivory, as we learn from the following lines of Martial:

Sic dentata sibi videtur Ægle
Emptis ossibus, Indicoque cornu

which Mr. Moore translates as follows:

So Ægle, with her bought and Indian bone,
May seem to have a second mouth of her own.

Mr. Moore is, we doubt not, a most skilful dentist, but we venture to say of him, as Dryden said of Swift, that he is not a poet.

The editor of the *Philadelphia Medical News*, in denouncing the use of such terms as "ii-para," "iii-para," "iv-para," "v-para," etc., to designate a multipara in her second, third, fourth, or fifth pregnancy, says, it seems strange that the inventiveness of medical philologists "has not been equal to the emergency of devising names for these simple facts, instead of designating them by an unpronounceable monstrosity." He suggests, "with proper fear and trembling," the coinage of suitable terms on the pattern of the existing "primipara" and "multipara"—thus, "duipara" or "deutipara" (which, by the way, should be "deuteripara," and even then would be a vile hybrid), "tripara," "quadripara," "quintipara," "sextipara," "septipara," "octipara," "nonipara," "decipara." But what about ladies who strive to act up to Napoleon's ideal of female "greatness," like those who are earning capitation grants of land for their lords in Canada by their fecundity? Are we to speak of them as "undevicesisimipara," "vicesimoquintipara," etc.?

The current issue of the *Gentleman's Magazine* contains an excellent article written by Mrs. J. E. Sinclair in view of the forthcoming meeting of the British Medical Association in London. She gives particulars of Linacre's life, and points out that the copy of his translation of Galen's *Methodus Medendi*, which he presented to Cardinal Wolsey, is at present in the British Museum, and that it contains an auto-

graph dedication from the great physician to the greater Cardinal. The authoress has obtained several new facts about the marriage and death of John Chambers, the first on the roll of the six physicians who formed the College of Physicians. She says that he was more remarkable for the religious preferment he had than for his position in medicine, but, like his contemporaries Butts and Vicary, we are perfectly familiar with his aspect, for has not his portrait been handed down to us in that masterpiece of Holbein, to whose impending sale we recently drew attention? John Chambers, it appears, was married to Jono Wardell in St. Margaret's Church, Westminster, November 9th, 1545; their son was christened in the following year, and Jono died in June, 1549; whilst on July 2nd, 1549, there is an item in the church-wardens' account books of "vinid" for "bille" paid at the burial of "Sir John Chamber." The author adds that the ordinary price for a funeral at this period appears to have been about 2d.

ASSOCIATION INTELLIGENCE.

NOTICE OF LAST QUARTERLY MEETING FOR 1895. ELECTION OF MEMBERS.

A MEETING of the Council will be held on October 23rd, 1895. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before the meeting—namely, October 2nd, 1895.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

FRANCIS FOWKE, General Secretary.

BRANCH MEETINGS TO BE HELD.

NORTH OF ENGLAND BRANCH.—The annual meeting of this Branch will be held on Thursday, July 25th, at 5 P.M., at the Royal Hotel, South Shields. Dr. Gump, President-elect, will deliver the annual address; and the officers of the Branch will be elected. The dinner after the meeting will take place at the Royal Hotel, at 6 P.M., 6s. 6d. each, wine not included. —G. E. WILLIAMSON, F.R.C.S., Honorary Secretary, 8, Eldon Square, Newcastle-on-Tyne.

GRAHAMSTOWN AND EASTERN PROVINCE BRANCH. The usual bimonthly meeting was held in the Albany General Hospital on Thursday, June 20th. Present, Dr. GREATHRAD, in the chair; Drs. Greenlees, Fitzgerald, Adam Becker, W. G. Atherstone, Edington, and Caldwell; Dr. Bruerton as visitor. *Minutes.*—The minutes of the previous meeting were read and confirmed.

Election of Branch Representative.—Dr. Edwin Atherstone was appointed the representative of the Branch on the Council for the ensuing year.

South African Medical Congress.—It was resolved that an invitation be issued to the South African Medical Congress to hold its next session in Grahamstown.

Papers.—Dr. FITZGERALD gave particulars of a case of unusual Fœtal Presentation; also of a case he had attended in which the lower jaw had been broken in several places, and which had been successfully treated by wire suturing.—Dr. CALDWELL read a paper on an outbreak of Fever, affecting chiefly the coloured population in Grahamstown. The subject gave rise to a great deal of discussion as to the nomenclature of the fever.

TRINIDAD AND TOBAGO BRANCH.

The annual general meeting of this Branch was held at the Colonial Hospital, Port of Spain, on June 19th, 1895; the Hon. Dr. J. A. DE WOLFE, President, in the chair. Drs. Mitchell, C.M.G., A. Lota, H. M. Alston, J. W. Eakin, W. V. M. Kosh, E. J. Read, S. M. Lawrence, E. N. Darwent, Louis Lota, A. P. Lange, J. A. Macfarlane, A. J. Perez, N. A. Rodriguez, O. B. Reid, J. R. Stollmeyer, R. Schmitt, and the Hon. Secretary, Dr. E. Prada, were present.

Report for 1894.—The report showed that the Branch had been in a quiescent state during 1894.

Election of President-elect.—Dr. Antoine Lota was elected, but declined on account of his limited acquaintance with the

English language. Dr. J. W. Eakin, of San Fernando, was then elected unanimously.

New Members.—The following were elected members: Hon. Dr. H. J. Lovell, C.M.G., Surgeon-General; Drs. A. Duprey, C.M.S., Farmin, Louis Lota, C. F. Lassalle, and J. A. Macfarlane.

President's Address.—The PRESIDENT read his inaugural address. After giving a brief history of the Branch, he referred in touching terms to the late President, Dr. Deaven Bake. He ended by exhorting the younger members not to lose the good opportunities for research which they had in this tropical colony.

New Rules.—The new rules submitted to the meeting by the Council were passed with a few amendments.

Communication.—Dr. ALSTON exhibited a specimen of Perforation of the Oesophagus in a child aged 2 years. The interesting point about the case was that on opening the chest the right pleural cavity was found to contain thirty ascarides, and, while the oesophagus and adjacent parts were being removed, five more ascarides were seen to wriggle out of the oesophagus through the opening, and pass into the right pleural cavity. The bowels contained several ascarides. The case was pronounced unique in the experience of those present.

BRITISH MEDICAL ASSOCIATION.

SIXTY-THIRD ANNUAL MEETING.

The sixty-third Annual Meeting of the British Medical Association will be held in London on Tuesday, Wednesday, Thursday, and Friday, July 30th, 31st, August 1st and 2nd, 1895.

President: E. LONG FOX, M.D. Oxon., F.R.C.P., Consulting Physician to the Bristol Royal Infirmary.

President-Elect: Sir J. RUSSELL RYNGOLDS, Bart., M.D., F.R.C.P., F.R.S., President of the Royal College of Physicians.

President of the Council: J. WARD COWINS, M.D. Lond., F.R.C.S., Senior Surgeon to the Royal Portsmouth Hospital.

Treasurer: HENRY TRENTHAM BUTLIN, F.R.C.S., D.O.L., Surgeon to St. Bartholomew's Hospital, E.C.

An Address in Medicine will be delivered by Sir WILLIAM BROADBENT, Bart., M.D., F.R.C.P., Physician-in-Ordinary to H.R.H. the Prince of Wales.

An Address in Surgery will be delivered by JONATHAN HUTCHINSON, F.R.S., F.R.C.S., Consulting Surgeon to the London Hospital.

An Address in Physiology will be delivered by EDWARD ALBERT SCHÄFER, F.R.S., Jodrell Professor of Physiology, University College.

The Scientific Business of the Meeting will be conducted in Fifteen Sections, as follows, namely:

A. MEDICINE.

Lecture Theatre—Conjoint Examination Hall.

President: F. W. PAVY, M.D., F.R.S. *Vice-Presidents:* Sir FREDERIC BATEMAN, M.D.; D. W. FINLAY, M.D.; W. S. CHURCH, M.D.; J. W. MOORE, M.D.; STEPHEN MACKENZIE, M.D.; E. MARKHAM SKERITT, M.D. *Honorary Secretaries:* WILLIAM COLLIER, M.D., St. Mary's Entry, High Street, Oxford; W. P. HERRINGHAM, M.D., 18, Upper Wimpole Street, W.; Sir HUGH R. BRVON, M.D., 18, Serjeant's Inn, Fleet Street, E.C.

The following subjects have been selected for discussion:—
Wednesday, July 31st.—1. Discussion on Diphtheria and its Treatment by the Antitoxin (embracing the following points: (1) Pathology of Diphtheria and its Sequelæ; (2) Symptoms and Progress; (3) Statistics of Mortality under the Antitoxin Treatment and under other Treatment; (4) Effect of the Antitoxin Treatment upon the Local Affection, upon the General Condition, and upon the Sequelæ; (5) Effects that may arise from the Antitoxin Treatment). Introduced by Sidney H. C. Martin, M.D. The following also intend to join in the discussion: G. Sims Woodhead, M.D.; E. W. Goodall, M.D.; Charles Mathison, M.D. (if possible); Alex. Johnston, M.D.; Professor von Bardeleben, Lecturer Breslau, M.D.; W. P. Herringham, M.D.; J. Campbell Hall, M.B.; W. Squire, M.D.

Papers by:

- DRESCHFELD, Julius, M.D. On Ataxic Paraplegia (Clinical Varieties and their Pathology).
 BRAYOR, C. E., M.D., and HORSLEY, V., F.R.S. On the Pathology of Severe Atrophies (Two Cases treated by Operation on the Cortex Cerebri).
 THURSTON, T. W., M.D. A Case of Gouty Dyspnoea.
 MURRAY, GEORGE, M.D. Notes on the Progress and Present Condition of the First Case of Myxoma treated by Thyroid Extract.
 WEST, Samuel, M.D. On the Treatment of Diabetes Mellitus by Uranium Nitrate.

HANOT, Professor. Notes sur le Diabète Bronzé.
 CAMPBELL, Colin, M.R.C.S. Notes on Direct Intrapulmonary Medication.

And, should there be time available:

- REDWICK, William, M.R.C.S. Notes on the Influence of Heredity in Disease.
 TAYLOR, Seymour, M.D. On the Connection between Chlorosis and Gastric Ulcer.
 ALDERSON, F. H., M.D. Latent Ulcer of the Stomach.
 JONES, E. Lloyd, M.D. Chlorosis.

Thursday, August 1st.—II. Discussion on Acute Lobar or Croupous Pneumonia, its Etiology, Pathology, and Treatment. Introduced by R. Douglas Powell, M.D. The following points will be suggested for special consideration:

Etiological.—1. How far chill arising from (a) low external temperature, (b) sudden change of external temperature, is causative of pneumonia. 2. How far the reception of a microbe is alone to be regarded as a sufficient cause of pneumonia. 3. How far pneumonia is a disease brought about by conditions favourable to the aggressive germination of an organism ever more or less present. 4. In what does septic or pythogenic pneumonia differ etiologically from the classical form of the disease? 5. Is infection a possible or considerable agency in the propagation of pneumonia?

Pathological.—Ultimate or minute pathology. 1. (F) A neuritis. 2. (F) A direct result of microbe toxins upon the lung parenchyma. 3. (F) The rôle of leucocytosis in pneumonia.

Therapeutical.—1. The value of a routine treatment in cases of moderate degree and favourable omen. 2. The value of certain modern methods and the indications for their employment. Pyrexia, the cardiac state, and microbic conditions will especially be held in view in discussing points of treatment.

The following gentlemen will join in the discussion: J. W. Washbourn, M.D.; A. G. Auld, M.D.; Julius Dreschfeld, M.D.; J. E. Pollock, M.D.; A. Foxwell, M.D.; W. J. Tyson, M.D.; G. W. Balfour, M.D.; A. Barrs, M.D.; Professor Bäumler (Freiburg); Professor Clifford Allbutt; Samuel Barton, M.D.; Sidney Coupland, M.D.; Samuel J. Gee, M.D.; G. A. Gibson, M.D.; Walter G. Smith, M.D.; Sir T. Grainger Stewart, M.D.; McCall Anderson, M.D.; Sinclair Coghill, M.D.; Lovell Drage, M.D.; David Finlay, M.D.; T. H. Green, M.D.; F. Hawkins, M.B.; H. McClure, M.D.; F. M. Pope, M.D.; E. Mackham Skerrett, M.D.; Shingleton Smith, M.D.; J. E. Squire, M.D.; William Squire, M.D.; W. R. Thomas, M.D.; and Samuel West, M.D.

Papers by:

- COHILL, J. Sinclair, M.D. The Hypodermic Use of Guaiacol in Acute Pulmonary Tuberculosis.
 FOXWELL, Arthur, M.D. Hypertrophic Cirrhosis of the Liver.
 MARAGLIANO, Professor. Sur le Traitement de la Tuberculose Pulmonaire avec la Sérothérapie Spécifique.
 SQUIRE, J. E., M.D. Influence of the Bacillary Theory of Tuberculosis on the Treatment of Phthisis.
 HANLEY, George, M.D., F.R.S. On the Formation of Calculi, particularly of Gall Stones.

And, should there be time available:

- LONGHURST, Arthur E., M.D. The Use of Alcoholic Stimulants and their Relation to True Physiological Health.
 SMITH, Winchester, M.D. The Weighing Machine in Diagnosis and Treatment.
 GILLES, H. Cameron, M.D. The Natural History of Pain.
 LANE, H., F.R.C.P. Chronic Rheumatic Arthritis: further points in differentiation from Chronic Rheumatoid Arthritis.

Friday, August 2nd.—III. Discussion on the Causes of Acute Rheumatism and its Relation to other Affections. Introduced by W. B. Cheadle, M.D. The following will join in the discussion: Archibald Garrod, M.D.; J. F. Goodhart, M.D.; Alfred Mantle, M.D.; J. T. MacLagan, M.D.; A. Newbholme, M.D.; P. G. Latham, M.D.; H. Handford, M.D.; Sir Dyce Duckworth, M.D.; A. Haig, M.D.; T. Churton, M.D.; H. Lane, M.D.; M. K. Hargreaves, M.D.; H. A. Caley, M.D.; M. Charteris, M.D.; Samuel West, M.D.; Stephen Mackenzie, M.D.; Gilbert Bannatyne, M.D.; A. P. Luff, M.D.; D. B. Lees, M.D.

Papers by:

- SHIMOLA, Professor. Sur la Toxicité des urines dans son degré et dans son mesographisme comme élément de diagnostic et de pronostic dans les maladies en général, et surtout dans les maladies aiguës infectieuses.
 MORISON, Alexander, M.D. The Treatment of Aortic Valvular Disease.
 CATON, R., M.D. On the Arrest of Endocarditis in Acute Rheumatism.
 THORNE, Bosly, M.D. On Certain Changes in the Cardio-vascular System which follow treatment by the Scott Methods.
 And, should there be time available:
 REYNOLDS, E. S., M.D. A Point in the Diagnosis between Chronic Rheumatism and Chronic Gout.
 PARSONS, Alfred, M.D. Arsenical Multiple Neuritis following the Application of a Cancer Cure.
 LAFFAN, P., M.D. Differential Diagnosis in Malignant Endocarditis, Typhoid Fever, and Acute Tuberculosis.

B. SURGERY.

Central Room, Second Floor—Conjoint Examination Hall.

President: Sir WM. MAC CORMAC, F.R.C.S. Vice-Presidents: T. BRYANT, F.R.C.S.; O. N. MACNAMARA, F.R.C.S.; REGINALD HARRISON, F.R.C.S.; A. WILLETT, F.R.C.S.; Sir W. STOKES, M.D.; MAYO ROBSON, F.R.C.S. Honorary Secretaries: J. D. HARRIS, M.R.C.S., 45, Southernhay, Exeter; J. BLAND SUTTON, F.R.C.S., 48, Queen Anne Street, W.; A. MARMADUKE SHEILD, F.R.C.S., 4, Cavendish Place, Cavendish Square, W.

The President will make some introductory remarks, in which he will refer to the Effects produced by Modern Rifle Bullets on the Human Body.

The following subjects have been selected for discussion:

1. The Diagnosis and Treatment of Fractures of the Upper Third of the Femur, including the Neck. To be introduced by Sir William Stokes, M.D., with lantern demonstration. The following gentlemen have intimated their intention of taking part in the discussion: Professor E. H. Bennett, M.D. (Dublin); Thomas Bryant, F.R.C.S. (London); Professor Chiene, M.D. (Edinburgh); H. H. Clutton, F.R.C.S. (London); J. Ward Cousins, M.D., F.R.C.S. (Portsmouth); Davies-Colley, F.R.C.S. (London); Damer Harrison, F.R.C.S. (Liverpool); Sir George Murray Humphry, M.D., F.R.S. (Cambridge); Mansell Moullin, F.R.C.S. (London); Howard Marsh, F.R.C.S. (London); Professor Macewen, M.D., F.R.S. (Glasgow); Rushton Parker, F.R.C.S. (Liverpool); Mayo Robson, F.R.C.S. (Leeds); Thos. Sinclair, M.D. (Belfast); F. A. Southam, F.R.C.S. (Manchester); Greig Smith, M.B. (Bristol); A. Willett, F.R.C.S. (London).

2. The Surgical Treatment of Cysts, Tumours, and Carcinoma of the Thyroid Gland and Accessory Thyroids. To be introduced by H. Trentham Butlin, F.R.C.S. (London). The following gentlemen have intimated their intention of taking part in the discussion: Professor Annandale, F.R.C.S. (Edinburgh); James Berry, F.R.C.S. (London); Thos. F. Chavasse, M.D. (Birmingham); R. C. Chicken, F.R.C.S. (Nottingham); Kendal Franks, M.D. (Dublin); Damer Harrison, F.R.C.S. (Liverpool); Victor Horsley, F.R.S. (London); Bowreman Jessett, F.R.C.S. (London); C. B. Keeley, F.R.C.S. (London); Professor Kocher (Bern); Dr. Krummer (Geneva); Jordan Lloyd, F.R.C.S. (Birmingham); R. H. Lucy, F.R.C.S. (Plymouth); Professor W. Macewen, M.D. (Glasgow); Rutherford Morison, F.R.C.S. (Newcastle-on-Tyne); James Murphy, M.D. (Sunderland); Mayo Robson, F.R.C.S. (Leeds); W. G. Spencer, F.R.C.S. (London); Sir William Stokes, M.D. (Dublin); Charters Symonds, M.D. (London); Thelwall Thomas, F.R.C.S. (Liverpool).

The following papers have been announced:

- ANDERSON, William, F.R.C.S. Three Cases of Sacral Hernia of the Sigmoid Flexure through the Left Inguinal Canal, with Anatomical Notes.
 BAKER, Mitchell, F.R.C.S. The Statistics of Modern Breast Operations.
 BROWN, G. Houston, M.R.C.S. A Hitherto Undescribed Locality in the Male Urinary Bladder where a Stone may lie and elude contact with any instrument introduced through the Urethra.
 CHAVASSE, Thos. F., M.D. A Successful Case of Removal of the Entire Upper Extremity for Injury by Berger's Method.
 CHRYSE, Watson, F.R.C.S., F.R.S. On Operations for Malignant Disease of the Pharynx and Naso-pharynx, with Cases.
 CRUICK, Harrison, F.R.C.S. A Complication occurring in Inguinal Colotomy.
 FRANKS, Kendal, M.D. On Movable Kidney.
 EVE, Frederic S., F.R.C.S. A Successful Case of Laparotomy for Intussusception in an Infant, with remarks.
 FENWICK, Hurry, F.R.C.S. A Series of Seventy Cases of Ablation of Tumours of the Bladder.
 KERN, John, M.D., F.R.C.S. Some Points in the Operative Treatment of Club Foot.

HONESTY, Victor, F.R.S. The Results of Operative Treatment of Injury or Disease of the Cervical Vertebrae.

KENNEDY, Kingston-Murdoch, Lieutenant-Colonel D. F., M.D. Rhinoplasty in India (Lantern Illustrations).

KERR, C. B., F.R.C.S. On Thirty Cases of Osteotomy of the Hip, with Cases.

KERR, E. Murdoch, F.R.C.S. Tarsotomy for Talipes Equinus in Adults and Adolescents.

LEITCH, Jordan, F.R.C.S. 1. On Gonorrhoeal Inflammation in and about the Scapular Vesicles. 2. On a Simple Method of Scouring the Tongue during Laryngeal Operations.

LEITCH, C. B., F.R.C.S. On the Treatment of Hydrocele by Incision.

MANN, Howard, F.R.C.S. The Pathology and Clinical History of some Rare Forms of Bony Ankylosis.

MORISON, Albert E. Notes on a Case of Jacksonian Epilepsy Treated by Trepanning.

MURPHY, C. A., F.R.C.S. Specimen showing the Junction made by Murphy's Button, Three Months after Operation, in the Case of Intestinal Anastomosis published in the BRITISH MEDICAL JOURNAL, April 20th, 1895.

MURPHY, J. H., M.D. (Chicago). Peritonitis.

MURPHY, James, M.D. On the Importance of Operating Early where an Operation is required in Abdominal Disease.

NEWMAN, W., M.D. (London). Symmetrical Necrosis of the Lower Third of Each Femur; Large Removal of Bone; Ultimate Amputation through the Last Third of Femur.

PAGE, Stephen, F.R.C.S. Two Cases of Suppurating Hydatid of the Liver drained through the Chest Wall.

ROBINSON, A. W. Mayo, F.R.C.S. A Series of Cases of Colectomy.

ROBINSON, W. Dunnett, F.R.C.S. (Edin.). 1. On Splenectomy, with Notes of Three Cases. 2. On Dilatation of Stricture of Oesophagus by Expanding Bougies.

WATSON, Spencer. A Case of Tachycardia Associated with Nasal Growths.

WATSON, Albert, M.D. The Treatment of Acute Pleural Effusion by Early Incision.

O. OBSTETRICS AND GYNAECOLOGY.

Large Theatre—King's College.

President: Sir WM. PRIESTLEY, M.D. **Vice-Presidents:** A. R. SIMPSON, M.D.; J. WATT BLACK, M.D.; Sir FRANCIS LAKING, M.D.; J. KNOWLESY THORNTON, M.B.; W. J. SINCLAIR, M.D.; M. HANDFIELD-JONES, M.D. **Honorary Secretaries:** W. S. A. GRIFFITH, M.D., 96, Harley Street, W.; A. H. F. BARBOUR, M.D., 4, Charlotte Square, Edinburgh; W. R. DAXIN, M.D., 57, Welbeck Street, W.

The following subjects have been selected for discussion:
The work of the Section has been provisionally arranged as follows:

Wednesday, July 31st:

10 A.M. President's Address. 10.30. Discussion: The Aseptic and Antiseptic Precautions to be Observed in Private Midwifery Practice, to be introduced by G. E. HERMAN, M.B., F.R.C.P. The following gentlemen are expected to take part in this discussion: Dr. STUART (Brooklyn), Professor LANK (New York), Dr. SMYLY, Professor SIMPSON, Dr. SWAYNE, Dr. PLAYFAIR, Professor BYERS, Dr. MORE MADDEN, Dr. WATT BLACK, Professor MURDOCH CAMERON, Dr. AUST-LAWRENCE, Dr. BOZAL, Dr. FORBES ROSS, and others.

Papers by:

APOSTOLI, Dr. (Paris). On Electro-therapeutics as a Means of Diagnosis in Gynaecology.

MADDEN, MORE, M.D. (Dublin). Gonorrhoeal Infection in some of its Gynaecological Aspects.

MORISON, ALBERT, M.D. (Sunderland). The Surgical Treatment of so-called Puerperal Fever.

Thursday, August 1st:

I.I.A.M. Papers by:

MARTIN, Professor (Berlin). Anterior Colpotoxy.

TAYLOR, J. W. F.R.C.S. (Manchester). Vaginal Colpotoxy.

DOUGLAS, A. M.D. (Manchester). A Case of Vaginal Colpotoxy for Tubal Pregnancy.

PIERCE, J. H., M.D. (London). Remarks on the Education and Training of Girls at and about the Period of Puberty.

SWAYNE, J. G., M.D. (London). The Treatment of Eclampsia occurring during Pregnancy, and Presenting no Signs of Labour.

Instruments will be shown by Professor LAZAREWITCH (St. Petersburg), Mr. F. STANMORE BISHOP (Manchester), and by Dr. LAFAN (Glasgow).

Specimens will be shown by Dr. Muret (Lausanne).

Friday, August 2nd:

10 A.M. Discussion: The Early Diagnosis of Malignant Disease of the Uterus, and the Treatment by Partial or Total Excision, to be introduced by J. Knowlesy Thornton, M.B.

The following gentlemen are expected to take part in this discussion: Professor MARTIN (Berlin), Professor POZZI (Paris), Professor LANK (New York), Mrs. SCHARLIEB, M.D. (London), Professor MURDOCH CAMERON, Dr. MORE MADDEN, Dr. MURPHY, Dr. SMYLY, Mr. J. W. TAYLOR, Dr. A. DONALD, Mr. ALBAN DORN, and others.

Papers by:

CAMERON, Professor MURDOCH (Glasgow). A New Theory as to the Position of Fetus in Utero.

BAMMOUR, A. H. FREELAND, M.D. (Edinburgh). The Changes in the Uterus during the Third Stage of Labour.

JASSETT, F. H., F.R.C.S. (London). A New Method of Performing Abdominal Hysterectomy for Fibroid Tumours.

DOUGLAS, A., M.D. (Manchester). Vaginal Hysterectomy for Fibroids.

FRANK, J. HOSACK (Bridge of Allan). Notes on a Case of Uterine Cystic Fibrosis.

The following papers have also been received, and will be read if time permits:

HAMPTON, A. H., M.D. (Hilkey, Leeds). Cases of Concealed Haemorrhage, Placenta Praevia, and Puerperal Eclampsia.

HELL, R., M.D. (Glasgow). The Use of Iodoform in the Treatment of Diseases of the Uterine Appendages.

CAMERON, Professor MURDOCH (Glasgow). Exceptional Gynaecological Experiences.

EDGE, F., M.D. (Wolverhampton). Radical Cure of Uterine Protrusion.

ROBERTS, LLOYD, M.D. (Manchester). Case of Tumour of the Fallopian Tube.

NAIRNE, Stuart, F.R.C.S. (Glasgow). Influence of Pregnancy on Uterine Fibroids.

NAPIER, Leith, M.D. (London). Some Complication of the Menopause.

NEWSHAM, W. H. C., M.B. (Clifton). Sterility.

TREVELYAN, Basil, M.R.C.S. (Bath). Labour in Young Primiparae.

D. PUBLIC MEDICINE.

Lower Hall—Exeter Hall.

President: ERNEST HART, D.O.L. **Vice-Presidents:** J. SPOTTISWOODE CAMERON, M.D.; C. H. W. PARKINSON, M.R.C.S.; WM. COLLINGRIDGE, M.D.; LOUIS C. PARKER, M.D.; P. BOOBYER, M.D.; JOHN O. THRESH, M.D. **Honorary Secretaries:** C. E. PAGE, M.R.C.S., Town Hall, Salford; REGINALD DUFFIELD, M.B., Sanitary Department, Vestry Hall, Harrow Road, Paddington, W.; F. W. CLARK, M.B., Lowestoft.

The regular business of the Section will commence each day with a formal discussion by gentlemen who have been invited to open the debates. The subjects selected are as follows:—

Wednesday, July 31st.—Presidential Address: Waterborne Disease and its Prevention. Discussion: The Regulation of the Slaughter of Animals for Human Food and the Inspection of Animals before and during Slaughter. Opener: T. M. LEGGE, M.D.

Papers by:

FARKAS, Dr. (Buda-Pesth). The late Visitation of Cholera in North-Eastern Districts of Hungary.

LAVIS, J. PARRY, F.I.C., and J. T. NRIEL, I.R.C.P. Ventilation of sewers.

WALDO, F. J., M.D., and WALSH, D., M.B. Underground Hakehouses.

POOR, G. V., M.D. Dry Method of Dealing with Urine.

SISLEY, R., M.D., PRINGLE, R., M.D., and GRAHAM, W., M.D. Smoke Abatement.

Thursday, August 1st.—Discussion: Hospital Isolation, House Quarantine, and Disinfection. Opener: P. BOOBYER, M.D.

Papers by:

KLEIN, Professor, F.R.S. and BIGGS, Hermann, M.D. Diagnosis of Doubtful cases of Diphtheria and the use of Bacteriology for that purpose.

BIGGS, Hermann, M.D. Use of Antitoxin for Immunising Members of Institutions.

NEWSHOLME, A. M.D. Extension of Schedule of Notification.

PIERCE, J. H., M.D. Enteric Fever as an Infectious Disease.

KENWOOD, H., M.B. Prevention of Milk Epidemics.

DIXEY, F. A., M.D. Vital Statistics of Diphtheria, 1891 & 1892.

BRAIDWOOD, F. M., M.D., and GREGORY, A. J., M.D. Hospital Accommodation by use of ships.

Friday, August 2nd.—Discussion: The Insecurity of Tenure of Extra-Metropolitan Medical Officers of Health under the Public Health Act, 1875. Opener: B. A. WHITEHEAD, M.D.

Papers by:

MENZIES, A. Campbell, M.B. The Need of Appointing Medical Officers of Health to County Councils.

PARKER, LOUIS, M.D. The Desirability of Appointing Medical Men as Superintendent Inspectors of Houses and Land.

CAMERON, J. SPOTTISWOODE, M.D. The Protection of Towns from the River.

NEWSHAM, T. G., M.D., and KENWOOD, H., M.D. Infectious and Zoonotic Diseases.

GRAHAM, W., M.D., and HENDER, T. G., M.D. The Vaccination Laws.

LAVIS, J. PARRY, F.I.C. Extension of the Army Compressive System to the Irish Poor Law Medical Service.

Owing to the amount of work to be done, readers of papers will be rigidly limited to fifteen minutes, and all other speakers to ten minutes. The names of those who have

signified their intention to speak will be announced in the Daily Programme.

E. PSYCHOLOGY.

East Wing Room, Second Floor—Conjoint Examination Hall.

President: W. J. MICKLE, M.D. **Vice-Presidents:** G. H. SAVAGE, M.D.; T. OLAYE SHAW, M.D.; D. NICOLSON, M.D.; HENRY RAYNER, M.D.; J. G. McDOWALL, M.D.; LIONEL A. WEATHERLY, M.D. **Honorary Secretaries:** JAMES CHAMBERS, M.D., 6 Mansfield Street, W.; T. SKYMOOR TUBE, M.B., 37, Albemarle Street, W.; JAMES TAYLOR, M.D., 34, Welbeck Street, W.

The President will open the Section with an Address on the Brain, on Wednesday, at 10 A.M.

A discussion has been arranged to take place on each day, namely:

Wednesday, July 31st.—On the Treatment of Melancholia, introduced by Henry Rayner, M.D. The following are expected to take part in the discussion: Dr. Blandford (London); Dr. Weatherly (Bath); Dr. Norman Kerr (London); Dr. Cooke (Worcester); Dr. Hayes (Newington); Dr. Hyslop (London).

Thursday, August 1st.—On Insanity, in Relation to Criminal Responsibility, introduced by H. Maudsley, M.D. The following have intimated their intention of taking part in this discussion: Professor Gairdner (Glasgow); Dr. Uguhart (Perth); Dr. Norman Kerr (London); Dr. Weatherly (Bath); Dr. Savage (London); Dr. Clouston (Edinburgh); Dr. Mercier (London); Dr. Shuttleworth (London).

Friday, August 2nd.—On Epilepsy, and its Relation to Insanity, introduced by W. R. Gowers, M.D. The following are expected to take part in this discussion: Professor Sir T. Grainger Stewart (Edinburgh); Dr. Buzzard (London); Dr. Clouston (Edinburgh); Dr. Dreschfeld (Manchester); Dr. Ferrier (London); Dr. Fletcher Beach (London).

The following gentlemen are also expected to participate in the work of this Section: Dr. P. W. Macdonald (Dorchester); Mr. Macphail (Derby); Dr. Henry Blake (Yarmouth); Dr. Outterson Wood (London); Dr. Hicks (London); Dr. Wiglesworth (Rainhill); Dr. Orange, O.B. (London).

The following papers have been announced:

BOND, C. H., M.D. The Relation of Diabetes to Insanity.
CAMPELL, A. W., M.D. A Comparison of the Breaking Strain of Ribs in the sane and Insane.

HEAD, H., M.D. Mental Symptoms in Relation to Bodily Diseases in the sane.

MAUDE, A., L.R.C.P. Mental Symptoms in Relation to Exophthalmic Goitre.

REYNOLDS, F. S., M.D. Mental Symptoms of Bodily Diseases.

SAVAGE, G. H., M.D., and CHARLES MERCINE, M.D. Insanity in Conduct.

SHAW, JAMES, M.D. The Early Symptoms of Insanity.

SHUTTLEWORTH, G. E., M.D. Operative Treatment of Idiotcy.

SMITH, Percy, M.D. Voluntary Boarders in Asylums.

WEATHERLY, L.A., M.D. The Law in Relation to Single Patients.

F. PHYSIOLOGY.

Physiological Laboratory—King's College.

President: DAVID FERRIER, M.D., F.R.S. **Vice-Presidents:** E. E. KLEIN, M.D., F.R.S.; WM. STIRLING, M.D.; DR. BUNGER BERGE, M.D.; J. BERRY HAYCRAFT, M.D. **Honorary Secretaries:** C. S. SHERRINGTON, M.D., F.R.S., Brown Institution, Wandsworth Road, S.W.; E. H. STARLING, M.D., 14, Grosvenor Road, S.W.

A discussion on the Mechanics of the Cardiac Cycle will be introduced by Professor Haycraft and D. Paterson, M.D. The following will take part: Noel Paton, M.D.; Lauder Brunton, F.R.S.; and Dr. Gibson.

The following papers have been announced:

BAYLIS, W. M., B.A., B.Sc., and Professor L. HILL. The Physics of the Cerebral Circulation.

BAYLIS, W. M., B.A., B.Sc., and E. H. STARLING, M.D. A New Method of Studying Vasomotor Changes.

BURCH, Professor de Burgh, M.D. On the Equipment of an Experimental Laboratory, with Exhibition of Apparatus.

FERRIER, T. GREGOR, M.D. The Work of Muscle. Decomposition Products from Gelatine and Collagen.

CAMPBELL, HARRY, M.D. The Resistance which the Capillaries offer to the Blood-flow.

ECCLIS, SYMONS, M.B. The Incidence of Leucocytes in the Urine in Health and Disease.

FERRIER, T. GREGOR, F. W., M.D. On the Perception of Luminosity at Different Parts of the Retina.

FERRIER, T. GREGOR, Professor, M.D., F.R.S. Nucleo-albumins.

HARLEY, VAUGHAN, M.D. Sugar as a Muscular Food.

JETTMAN, Professor. (1) Innervation du Cœur. (2) Sur les Echanges Nutritifs Pendant l'Inanition.

HUNTER, William, M.D. Experiments relating to the Functions of the Optic Nerve.

KENT, A. F. Stanley. On Outlying Cells in the Optic Chiasma and in the Optic Tract.

LEATHES, T. B., F.R.C.S. On the Interchange of Fluid between the Blood and the Tissues.

MARINESCO, Dr. On Tertiary Atrophy and Degeneration of the Central Nervous System.

PENHURRY, M. B., M.B. The Physiology of Heat Regulation.

PICKARD, J. W., M.D. Intravascular Coagulation produced by Synthesised Protoid-like Substances.

RAVENHILL, W., L.R.C.P. Mechanical Coagulation of Proteids.

STEWART, Professor G. N. Further Researches on Circulation Time.

STOKVIS, Professor. The Influence of Sugar on Muscular Work.

TURNER, W. Aldren, M.D. (1) The Results of Lesions of the Tuberculum Caudale. (2) The Results of Section of the Trigeminal Nerve and the Consequent Degenerations.

TURNER, Aldren, M.D. Demonstration of Several Recently Described Tracts in the Brain and Spinal Cord.

Communications have also been promised by Professor Allen, Dr. Haldane, Dr. Paterson, and others.

G. ANATOMY AND HISTOLOGY.

Chemical Theatre—King's College.

President: HENRY MORRIS, F.R.C.S. **Vice-Presidents:** A. MACALISTER, M.D., F.R.S.; W. J. WALSHAM, F.R.C.S.; A. H. YOUNG, F.R.C.S.; B. C. A. WINDLE, M.D.; G. I. MAKINS, F.R.C.S.; A. W. HUGHES, F.R.C.S. **Honorary Secretaries:** F. G. PARSONS, F.R.C.S., St. Thomas's Hospital, S.E.; C. B. LOCKWOOD, F.R.C.S., 19, Upper Berkeley Street, W.

The following subjects have been selected for discussion:—

Wednesday, July 31st.—Art in its Relation to Anatomy, to be opened by Professor William Anderson, F.R.C.S., Joint Lecturer on Anatomy at St. Thomas's Hospital, Professor of Anatomy in the Royal Academy of Arts.

Thursday, August 1st.—The Development and Structure of the Placenta, to be opened by Professor A. H. Young, M.B., F.R.C.S., Professor of Anatomy at Owens College, Manchester.

Friday, August 2nd.—The Topographical Anatomy of the Abdomen, to be opened by Professor A. Thomson, M.A., Professor of Anatomy at Oxford University.

The following papers have been announced:—

GRIFFITHS, J., M.A., F.R.C.S. On the Anatomy of the Genito-urinary Apparatus in the Pig and Boar, with Remarks on the Effects of Castration.

HIGGINS, H., M.R.C.S. On the Mechanism of the Knee.

KENT, A. F., M.D. On Synostosis of the Mesosternum to the Preosternum in Man and Anthropoids, considered as to its Prevalence among them and its Value as Evidence of their Genetic Relationship.

KENT, A. F. Stanley, M.A. On the Histology of the Generative Organs in a Hermaphrodite Dog.

PATERSON, Professor A. M., M.D. On the Position of the Kidneys.

PAYNE, J. F., M.D. On an English Anatomical Manuscript of the 14th Century. (Some old anatomical works will also be exhibited.)

ROBINSON, A., M.D. Demonstration of the Structure of the Placenta in Carnivora and Rodentia.

SMITH, T. Manners, B.A., M.R.C.S. (1) On some points in the Anatomy of Three Symmetrical Monsters; (2) Notes upon the Supernumerary Elements of the Embryonic Hand and Foot.

WINDLE, Professor. Note on the Eustachian Tube.

H. PATHOLOGY AND BACTERIOLOGY.

South Room, Ground Floor—Conjoint Examination Hall.

President: SAMUEL WILKS, M.D., F.R.S. **Vice-Presidents:** J. M. PURSER, M.D.; J. F. GOODHART, M.D.; SIDNEY COUPLAND, M.D.; R. SAUNDY, M.D.; W. WATSON CHEYNE, F.R.C.S.; ANTHONY A. BOWLEY, F.R.C.S. **Honorary Secretaries:** S. G. SHATTOCK, F.R.C.S., St. Thomas's Hospital, S.E.; H. D. ROLLESTON, M.D., 13, Upper Wimpole Street, W. The work of the Section has been arranged as follows:

Wednesday, July 31st.

10 A.M.—Introductory Remarks by the President.

10.30 A.M.—Demonstration of the Malaria Parasite by P. Manson, M.D., with Some Facts as to its Life-history. (Illustrated by Lantern Slides.) A discussion will follow, in which it is hoped the following will take part: Professor Crookshank; A. A. Kanthack, M.D.; and G. Thin, M.D. (who will give a demonstration before the discussion).

11.15 A.M.—A. Foxwell, M.D., on Exophthalmic Goitre; G. R. Murray, M.D., Some Results of Thyroidectomy.

11.45 A.M.—Mr. J. H. Targett, on Syringomyelia and Joint Disease.

12.0 P.M.—J. Risien Russell, M.D., on Congenital Defects of the Cerebellum.

12.15 P.M.—Dr. Robertson, on Arachnoid Haemorrhage.

12.30 P.M.—Papers on Cancer and other New Growths. The

following will read papers or take part in the discussion: R. Hewlett, M.D., On the Chemistry of Carcinoma and Sarcoma; D'Arcy Power, F.R.C.S.; H. Snow, M.D., The Insidious Mucous Infection of Breast Carcinoma; G. Thin, M.D.; Mr. T. W. Blake, The Occurrence of Cancer in Chalk Valleys; W. Roger Williams, F.R.C.S., On Uterine Neoplasms and their relative frequency; Dr. Brathwaite, Fungi in Malignant Disease; E. C. Bousfield, L.R.C.P.; T. N. Kelyack, M.D.

1.45 p.m. A. R. Parsons, M.B., Specimen of Larynx from case of Typhoid Fever.

Thursday, August 1st.

10 a.m.—Discussion on Neuritis. Introduced by S. J. Sharkey, M.D. The following have promised to read papers or to join in the discussion: F. W. Mott, M.D.; W. M. Ord, M.D.; Professor Trevelyan, M.D.; Russell Wells, M.B.; W. H. Wilson, M.B.

11.30 a.m.—Discussion on Vaccinia and Variola. Introduced by S. Monckton Copeman, M.D. It is hoped that T. D. Acland, M.D.; S. Coupland, M.D.; Professor Crookshank, M.B., and others will take part in the discussion.

12.30 p.m.—Discussion on Pernicious Anæmia. Introduced by Dr. W. Hunter, and Dr. Monckton Copeman will speak.

1 p.m.—Dr. Allan Macfadyen, The Formation of Methyl-Mercaptan on the Body and its Production by Bacteria.

1.15 p.m.—Paper by Professor Adami: The Effect of the Reactions of Media upon the Pathogenic Properties of Bacteria.

1.45 p.m.—Paper by A. G. Auld, M.D., on Hematogenous Jaundice.

1.55 p.m.—P. Furnivall, L.R.C.P., on Acromegaly.

Friday, August 2nd.

10 a.m.—Discussions on Lymphadenoma. Introduced by W. G. Spencer, F.R.C.S. The following have intimated their intention to take part in the discussion: W. J. Fenton, M.B.; H. Morley Fletcher, M.D.; R. M. Leslie, M.B.; A. A. Kanthack, M.D.; Mr. F. S. Eve; Mr. J. Jackson Clarke; O. A. Morton, F.R.C.S.; G. N. Pitt, M.D.; D'Arcy Power, F.R.C.S.; H. Snow, M.D.; G. Thin, M.D.; Claud Wilson, M.D.

11.30 a.m.—Papers on Leprosy. By P. Abraham, M.D.; G. Thin, M.D.

12 noon.—Professor Babes.

12.15 p.m.—Professor Crookshank on Actinomycosis.

12.30 p.m.—R. Hewlett, M.D.—The Mucosa Reaction in Typhoid Fever. F. F. Westbrook, M.D.—The Growth of the Cholera Vibrio and other Bacilli in Sunlight. R. Hewlett, M.D., and St. Clair Thomson, M.D.—On the Fate of Micro-organisms in Inspired Air.

1.30 p.m.—F. R. Walters, M.D.—Pulmonary Hypertrophic Osteoarthropathy.

A. Macfadyen, M.D., and R. Hewlett, M.D., will exhibit Cultures and Bacteriological Specimens.

The Secretaries venture to ask gentlemen who intend to show microscopic specimens to let them know the number of microscopes (and the powers) necessary to illustrate their papers, as this will be limited; and also to state whether the use of a lantern is required.

A separate room will be provided for the exhibition of macroscopical and other specimens; lantern demonstrations will be given in the meeting room.

I. OPHTHALMOLOGY.

Large Committee Room, Ground Floor—Conjoint Examination Hall.

President: H. POWER, F.R.C.S. Vice-Presidents: D. ARGYLL ROBERTSON, M.D.; W. A. BRADLEY, M.D.; G. ANDERSON CRITCHETT, M.A., F.R.C.S. Edin.; W. ADAMS FROST, F.R.C.S.; A. EMERY JONES, M.D.; A. H. BENSON, M.B. Honorary Secretaries: R. W. DOYNE, F.R.C.S., Kilmoro, Oxford; E. TREACHER COLLINS, F.R.C.S., 54, Wimpole Street, W.; W. T. HOLMES STILES, F.R.C.S., 17, Welbeck Street, W.

The following discussions have been arranged:

July 21st.—On Certain Rare Cases of Recurrent Ophthalmia. The affection occurs in adults; it begins with conjunctival and ciliary injection, general or limited, myosis, slight transient myopia, with oedema of the lids in some cases, and occasionally vesicles on the cornea. The duration varies from twenty-four hours to a few days, and recurrence takes place at varying intervals. It is probably angio-neurotic in its origin. The discussion will

be opened by Professor E. Fuchs (Vienna), and continued by G. A. Berry, F.R.C.S. (Edinburgh), J. Griffith, F.R.C.S. (London), John Hearn, M.D. (Darlington), and A. Emrys Jones, M.D. (Manchester).

August 1st.—On the Diagnosis of Orbital Growths. Opened by H. R. Swanzy, F.R.C.S. (Dublin); and Professor Panas (Paris). Continued by G. A. Berry, F.R.C.S. (Edinburgh); W. J. Collins, M.D., F.R.C.S. (London); Hill Griffith, M.D. (Manchester); G. Hartridge, F.R.C.S. (London); H. Macnaughton Jones, M.D. (London); H. Juler, F.R.C.S. (London); J. B. Lawford, F.R.C.S. (London).

August 2nd.—On the Question of Operating in Chronic Glaucoma. Opened by E. Nettleship, F.R.C.S. (London). Continued by G. A. Berry, F.R.C.S. Edin.; G. Anderson Critchett, F.R.C.S. Edin. (London); Adams Frost, F.R.C.S. (London); G. E. Glascott, M.D. (Manchester); John Griffith, F.R.C.S. (London); G. Hartridge, F.R.C.S. (London); H. Macnaughton Jones, M.D. (London); H. Juler, F.R.C.S. (London); C. G. Lee, M.R.C.S. (Liverpool); D. Little, M.D. (Manchester); G. Mackinlay, F.R.C.S. Edin. (London); Priestley Smith, M.R.C.S. (Birmingham); H. R. Swanzy, F.R.C.S. (Dublin); Spencer Watson, F.R.C.S. (London); R. Williams, M.R.C.S. (Liverpool); W. J. Cant, M.R.C.S. (Lincoln); A. Bronner, M.D. (Bradford); W. H. H. Jessop, F.R.C.S. (London); Professor Galezowski (Paris).

The following papers have been announced:

BRAMMONT, W. M., M.R.C.S. On the Question of Latent Hypermetropia in the Visual Examination of Candidates for the Public Services.

BENSON, A. H., F.R.C.S. Acromegaly with Ocular Complications.

BERRY, G. A., F.R.C.S. On Injection of Chlorine Water into the Vitreous.

BICKERTON, T., M.R.C.S. (Liverpool). The Upper Segment of the Eyeball.

Question in Board of Trade Official Inquiries into Shipping Disasters.

BULL, Geo. J., M.D. (Paris). Optometry by the Subjective Method.

DONALDSON, E., L.R.C.P. (Londonderry). Case of Acute Glaucoma.

occurring in a patient with Advanced Carcinoma of the Rectum.

EDRIDGE-GREEN, F. W., F.R.C.S. (London). Tests for Colour Blindness.

FUCHS, Professor E. A New Theory of Erythroptosis.

GRIFFITH, John, F.R.C.S. Choroidal sarcoma in Infancy.

HARTHIDGE, G., F.R.C.S. Gonococcal Strabismus.

JESSOP, W. H. H., F.R.C.S. (London). Membranous Conjunctivitis.

JONES, H. Macnaughton, M.D. (London). Cases illustrative of the importance of the Correction of Errors of Refraction in Neurasthenic Women.

JULIER, H., F.R.C.S. (London), and HARRIS, W. J. Case of Carcinomatous Tumour of the Body of the Sphenoid causing Blindness of Both Eyes.

JULIER, H., F.R.C.S., and SMALL, Morton, M.R.C.S. Case of Acute Orbital Cellulitis following Dental Abscess implicating the Antrum of Highmore.

LEE, Charles, L.R.C.P. Cases of Pemphigus and Essential Strabismus of the Conjunctiva.

MACGILLIVRAY, A., M.D. (Dundee). Hereditary Congenital Nystagmus.

MACRAY, Geo., F.R.C.S. Edin. A Note on the Surgical Treatment of Dislocated Lens.

RUSSELL, J. S. Histen, M.D. (London). The Influence of the Cerebrum and Cerebellum on Eye Movements.

SCOTT, Kenneth, M.B. (Calcutta). Radical Operative Treatment of Trichiasis.

The following gentlemen have also promised to take part in the proceedings: E. F. Drake-Brockman, M.D. (London); Professor Galezowski (Paris); Professor Gayet (Lyons); Professor Meyer (Paris); A. MacGillivray, M.B. (Dundee); Simeon Snell, F.R.C.S. Edin. (Sheffield); A. M. Ramsay (Glasgow).

The following gentlemen will show specimens in the Museum: E. Treacher Collins, F.R.C.S.; John Griffith, F.R.C.S.; G. Hartridge, F.R.C.S.; H. Juler, F.R.C.S.; D. Marshall, F.R.C.S.; R. W. Doyme, F.R.C.S.; W. J. Cant, M.R.C.S. (Lincoln).

W. Adams Frost, F.R.C.S. (London) will give a lantern demonstration of ophthalmoscopic pictures at noon on August 1st.

J.—DISEASES OF CHILDREN.

Theological Class Room—King's College.

President: JOHN H. MORGAN, F.R.C.S. Vice-Presidents: W. B. CHADWICK, M.D., F.R.C.P.; F. A. SOUTHAM, F.R.C.S.; H. HANDFORD, M.D.; W. ARBUTHNOT LANE, M.S., F.R.C.S.; A. FOXWELL, M.D., F.R.C.P.; D'Arcy Power, F.R.C.S. Secretaries: DAWSON WILLIAMS, M.D., F.R.C.P., 25, Old Burlington Street, London, W.; HUGH R. JONES, M.D., 88a, Grove Street, Liverpool; HERBERT F. WATERHOUS, F.R.C.S., 51, Wimpole Street, London, W.

The following are the arrangements for this Section. The dates and order of the discussions will be adhered to as closely as circumstances permit.

Wednesday, July 27th.

A discussion on Congenital Syphilitic Manifestations in Bones and Joints, to be opened by the President of the

Section, John H. Morgan, F.R.C.S. Howard Marsh, F.R.C.S., H. H. Clutton, F.R.C.S., Anthony Bowlby, F.R.C.S., Robert Jones, F.R.C.S. (Liverpool), H. B. Robinson, M.D., Frederic Eve, F.R.C.S., and Leopold Hudson, F.R.C.S., intend to take part in the discussion, and O. A. Ballance, F.R.C.S., and H. Stansfield Collier, F.R.C.S., will contribute a series of cases.

A discussion on the Treatment of Hernia in Children, to be introduced by Hashten Parker, F.R.C.S. (Liverpool). Sir William Stokes, M.D., Ward Cousins, M.D., F.R.C.S. (President of Council), Professor William Macewen, F.R.S. (Glasgow), Professor Crichton (Edinburgh), Mitchell Banks, F.R.C.S. (Liverpool), W. Alexander, F.R.C.S. (Liverpool), F. A. Southam, F.R.C.S. (Manchester), Jordan Lloyd, F.R.C.S. (Birmingham), J. Macready, F.R.C.S. (London), D'Arcy Power, F.R.C.S., W. Arthurthor Lane, M.S., F.R.C.S., C. B. Lockwood, F.R.C.S., H. P. Symonds, F.R.C.S. (Oxford), Herbert Waterhouse, F.R.C.S., George Heaton, M.D. (Birmingham), Damer Harrison, F.R.C.S. (Liverpool), W. G. Elack, F.R.C.S. (Newcastle), and Reginald H. Lacy, F.R.C.S. (Plymouth), intend to take part in this discussion.

The following papers will be read:

LOCKWOOD, W. G., F.R.C.S. Hernia of the Ovary in an Infant with Torsion of the Pedicle.
THOMSON, John, M.D. (Edinburgh). Congenital Hypertrophy of the Pylorus and Duodenum.
GILBERT, R. A., M.D. On Renal Colic in Infants.
LLOYD, Jordan, F.R.C.S. On Nephrectomy in Children.

Thursday, August 1st.

A discussion on the Nervous Sequelae of Acute Infectious Diseases in Children will be introduced by H. Handford, M.D. (Nottingham), and continued by W. E. Gowers, M.D., F.R.S., Thomas Barlow, M.D., W. B. Cheadle, M.D., Jules Comby, M.D., (Paris), Professor v. Ranke (Munich), E. Robertson, M.D. (Liverpool), James Taylor, M.D., William Hunter, M.D., H. B. Donkin, M.D., T. More Madden, M.D. (Dublin), Fletcher Beach, M.B., F. W. Mott, M.D., Montagu Murray, M.D., W. S. Colman, M.D., and Dawson Williams, M.D.

The following papers will be read:

GARROD, Archibald E., M.D., F.R.C.P., and FLETCHER, Morley, M.D. On the Maternal Factors in the Causation of Rickets.
BARTON, J. Kingston, M.R.C.P. (London). The Relation between the Foods of Early Life and the Condition of the Teeth in Youth and Early Adulthood.
BELLANTYKE, J. W., M.D. (Birmingham). The Relation of Certain Diseases of Infancy to Adult Malacostomus and Epiglottitis.
COMBY, Dr. J. (Paris). The Non-pathogenic Streptococci and Staphylococci of the Throat in Children.
TRELFOED-SMITH, Thomas, M.D. (Royal Albert Asylum, Lancaster). The After-History of Two Cases of Craniostomy.
CAULLEY, Edmund, M.D. On the Value of Trophing in Tuberculous Meningitis.

Friday, August 2nd.

A discussion on Doses of Various Remedies suitable for Children at the Several Ages, to be introduced by J. Kingston Barton, M.R.C.P. D. J. Leech, M.D. (Manchester), J. Mitchell Bruce, M.D., H. B. Donkin, M.D., A. Foxwell, M.D. (Birmingham), N. J. Tirard, M.D., Neville Wood, M.R.C.P. (London), and T. More Madden, M.D. (Dublin) intend to take part in this discussion.

The following communications will be made:

GRATTAN, Nicholas, F.R.C.S.I. (Cork). Demonstration of Osteoclasia.
CARR, J. Walter, M.D. A Protest against the use of the term "Consumptive Bowels."

It is proposed also to arrange for the demonstration of cases of interest on each day; among these will be:

CLARK, J. Jackson, M.B. (London). Congenital Syphilis with Ulceration of Tongue.
EVE, Frederic, F.R.C.S. (London). (1) Spina Bifida cured by Excision of Sac. (2) Congenital Dislocation of Shoulder backwards treated by Operation.
MORGAN, J. H., F.R.C.S. (President). A Series of Cases of Excision and Erasion of the Knee-joint.

K. OTOLOGY.

Room 22—King's College.

President: Sir W. DALBY, F.R.C.S. Vice-Presidents: CHARLES WARDEN, M.D.; G. P. FIELD, M.R.C.S.; E. CRESSWELL BARR, M.B.; J. DUNDAS GRANT, M.D.; EDWARD LAW, M.D.; O. A. BALLANCE, F.R.C.S. Honorary Secretaries: O. E. L. B. HUNSON, F.R.C.S., 16, Harley Street, W.; G. C. WILKIN, L.R.C.P., 39, Weymouth Street, W.

Wednesday, July 31st.—A discussion on the Treatment of the Various Forms of Nerve Deafness. Opened by J. Dundas Grant, M.D., F.R.C.S.

Thursday, August 1st.—Discussion on Cerebral Complica-

tions in relation to Middle Ear Disease. Opened by Professor Macewen, M.D., C.M., F.R.S., LL.D., Regius Professor of Surgery, University of Glasgow.

The following gentlemen have signified their intention of taking part in these discussions: W. Milligan, M.D.; George Heaton, F.R.C.S.; Dr. Luc (Paris); A. M. Sheild, F.R.C.S.; G. W. Hill, M.D.; Lewis Jones, M.D.; H. Macnaughton Jones, M.D.; W. Downie, M.D.; Thomas Barr, M.D.; L. H. Pegler, M.D.; P. McBride, M.D.; J. Walton Browne, M.D.; Farquhar Matheson, M.D.

Papers will be contributed and Specimens exhibited by the following amongst others:

BARR, E. Cresswell, M.B. will show (1) a Dummy for Teaching Palpation of the Naso-Pharynx. (2) A case of Objective Pulsating Tumor of the Middle Ear. The Treatment of Intractable Suppurations of the Middle Ear by Operation through the Mastoid.
BRENNER, Adolph, M.D. Notes of Five Cases of Disease of Altit treated by Modified Slack's Operation.
COUSINS, J. Ward, M.D., F.R.C.S. On the Use of Artificial Tympanic Membranes.
GOVE, Professor. On a not yet described Form of Rotatory Sensation in Patients suffering from Labyrinthitis Interna.
HILL, G. V., M.D. will show specimens.
JONES, Lewis, F.R.C.S. Edin. On Turbidity in Cases of Deafness and Tinnitus Aurium.
JONES, H. Macnaughton, M.D. (1) On some Otolological Considerations in the Treatment of Nerve Deafness. (2) Brief Notes of a Case of Hyper-methaemia Acanthia.
LACE, Richard, F.R.C.S. On the Anatomical Connections of the Tympanic Membrane, with a few Remarks on their Pathological Importance. Specimens will be exhibited to illustrate this paper.
LAW, Edward, M.D. will exhibit some Preparations sent by Professor Politzer.
LAWRENCE, L. A., F.R.C.S., will also show some Normal Bone Preparations made by Professor Politzer.
MACALISTER, George, M.B. will show a Portable Electric Light Battery and Laryngoscope.
MACDONALD, William, M.D. Tuberculous Disease of the Mucosa Membrane of the Middle Ear and its Adnexa: an experimental investigation. Diagrams and Specimens will be exhibited to illustrate this paper.
PEGLER, L. H., M.D. will show Microscopic Sections illustrating the Histology of Tubercinal and Septal Hyperplasia.
PRITCHARD, Urban, M.D. Microscopical Specimens of Aspergillus.
SCATLIFE, J. M. E., M.D. On the Use of the Pneumatic Speculum in the Treatment of Diseases of the Ear.

L. PHARMACOLOGY AND THERAPEUTICS.

East Wing Room, Ground Floor—Conjoint Examination Hall.

President: Sir WILLIAM ROBERTS, M.D., F.R.S. Vice-Presidents: J. TALFOURD JONES, M.B.; T. LAUDER BRUNTON, M.D., F.R.S.; J. MITCHELL BRUCE, M.B.; W. HALL WHITE, M.D.; DONALD MACALISTER, M.D.; M. McILHUGH, M.B. Honorary Secretaries: VAUGHAN HARLEY, M.D., 16, Harley Street, W.; W. SOLTAN FENWICK, M.D., 10, Devonshire Street, W.

Wednesday, July 31st.

10 A.M. The President's introductory remarks. 10.15 A.M. Discussion upon Serum Therapeutics: Dr. Klein. 10.35 A.M. Dr. Washbourn. 10.55 A.M. Professor Fraser. 11.5 A.M. Dr. Charteris. 11.15 A.M. Dr. Hewlett. 11.25 A.M. Dr. Tirard. 11.35 A.M. Dr. Sidney Phillips. 11.45 A.M. Dr. GASTON. 11.55 A.M. Dr. Coliger. 12.5 P.M. Mr. Bokenham. 12.15 P.M. Dr. Goodall. 12.25 P.M. Dr. Bruce. 12.35 P.M. Dr. MacCombie. 12.45 P.M. The opener's reply.

Papers by:

FRASER, Professor. The Antitoxin of Snake Poison.
BOKENHAM, T. J., M.R.C.S. The Antitoxin of Erysipelas.
APOSTOLI, Professor. The Therapeutic Value of Alternating Currents of High Frequency.
MOSSE, Professor. (1) The Therapeutic Action of Formaline. (2) The Interchange of Gases in the Lung at High Altitudes.
OLIVER, George, M.D. The Therapeutic Use of Suprarenal Capsules.
OTTOLENGHI, Professor. The Therapeutic Value of Calomel followed by Salt and Acid Substances.
ROSENDAHL, Professor. (Title not yet communicated.)

Thursday, August 1st.

10 A.M. Discussion on the Requirements of the Profession with reference to the Revision of the *British Pharmacopoeia*: Dr. Leech. 10.20 A.M. Professor Donald MacAlister. 10.30 A.M. Professor Bradbury. 10.40 A.M. Dr. Page. 10.50 A.M. Dr. Talfourd Jones. 11 A.M. Dr. Charteris. 11.10 A.M. Dr. W. Carter. 11.20 A.M. Dr. C. Pearson. 11.30 A.M. Dr. Tirard. 11.40 A.M. Dr. Neville Wood. 11.50 A.M. Dr. Thomas Oliver. 12. Dr. H. G. Lys. 12.10 P.M. Dr. A. Kinsey-Morgan. 12.20 P.M. Dr. W. Armstrong. 12.30 P.M. Dr. Ralph Stockman. 12.40 P.M. The opener's reply.

Papers by:

BALFOUR, George, M.D. Therapeutics of the Digitalis Group.
PHILLIPS, C. F., M.D. The Pharmacological Action of Berberine.

SMART, Gordon, M.D. Notes on the Action of the Mydriatic Group.
 SMITH, Thomas, M.D. The Dietetic Treatment of Toxicosis.
 SMITH, E. M.D. Therapeutic Action of Foods in Diseases of Children.
 SMITH, E. M.D. The Therapeutic Value of Massage.
 SMITH, S. F. M.D., and BARRETT, Vaughan, M.D. The Action of a
 Sodium Salt in the Treatment of Intestinal Antisepsis.
 FOSBROOK, W. Bolton, M.D. Intestinal Antisepsis.
 Friday, August 2nd.

Papers by:
 10 A.M. CUYVE, Robert, M.R.C.S. Therapeutic Value of the Waters of
 Widdow's Spa.
 10.15 A.M. EARNLEY-WILMOT, R., M.B. Therapeutic Value of the Waters
 of Loughborough Spa.
 10.30 A.M. FOX, Fortescue, M.D. Therapeutic Uses of the Waters of
 Strathpeffer Spa.
 10.45 A.M. HYDE, Samuel, M.D. Therapeutic Value of the Waters of
 Tiverton.
 11 A.M. MYSTER, A. E., M.D. Therapeutic Value of the Waters of Harro-
 gate.
 11.15 A.M. SPENCER, J. Kent, M.D. Therapeutic Value of the Waters of
 Bath.
 11.30 A.M. TOMLINS, W. M.R.C.S. The Brine Baths of Epsom and
 Hove. A. C. E. M.P. Value and Use of the Waters.
 ARTHURSON, W. M.R.C.S. The Therapeutics of Rheumatoid Arthritis.
 HARRIS, Vincent, M.D. Cerebral in Pulmonary Disease.
 WALTERS, F. H., M.D. The Subcutaneous Use of Quinine.
 THORNTON, S. M.D. The Treatment of Uterine Dyspepsia.
 RYAN, Herbert, M.D. London.
 HILLINGWORTH, C. R., M.D. Tabellae and Tablids, their Uses and
 Abuses.
 OVERLAND, Walker, M.B. Arsenic and Belladonna in Chorea.
 GOODBODY, F. W. M.D., and EARNLEY, Vaughan, M.D. Action of Piper-
 cine on Uric Acid in the Urine.

M. LARYNGOLOGY.

North Room, Ground Floor—Conjoint Examination Hall.

President: FRANK SEMON, M.D. Vice-Presidents: Sir
 PHILIP SMYLY, M.D.; W. MACNELL WHISTLER, M.D.;
 F. DE HAVILLAND HALL, M.D.; GERVILLE MACDONALD,
 M.D.; SCANNES SPICER, M.D.; A. W. SANDFORD, M.D. Honorary
 Secretaries: J. MIDDLEMASS HUNT, M.B., 55, Rodney Street,
 Liverpool; ST. CLAIR THOMSON, M.D., 28, Queen Anne Street,
 W.; E. B. WAGGETT, M.B., 68, Park Street, W.

The following subjects have been selected for discussion:
 Wednesday, July 31st.—The Etiology of Mucous Polypi
 of the Nose, introduced by Professor Guye (Amsterdam), Dr.
 Luc (Paris), and Dr. McBride (Edinburgh).

Thursday, August 1st.—The Infectious Nature of Lacunar
 Tonsillitis, introduced by Professor B. Fraenkel (Berlin),
 and Dr. J. MacIntyre (Glasgow).

Friday, August 2nd.—The Indications for Early Radical
 Operation in Malignant Disease of the Larynx, introduced by
 Dr. Bryson Delavan (New York), and Mr. H. T. Butler (London).

The following members have expressed their intention of
 joining in the discussions:

F. Mark Howell, F.R.C.S. Ed., R. Lake, F.R.C.S., L. H. Pegler,
 M.D., A. Hodgkinson, M.D. (Manchester), W. Milligan, M.D.
 (Manchester), Charles Warden, M.D. (Birmingham), and R.
 Mackenzie Johnston, M.D. (Edinburgh). S. M. Spicer,
 M.D., and William Hill, M.D., on July 31st. F. Mark Howell,
 F.R.C.S. Ed., A. Hodgkinson, M.D., Charles Warden, M.D.,
 Watson Williams, M.D. (Bristol), Adolf Bronner, M.D. (Brad-
 ford), Scanness Spicer, M.D., and W. Hill, M.D., on August 1st.
 Philip de Santis, F.R.C.S., A. Hodgkinson, M.D., Charles
 Warden, M.D., and Robert H. Woods, M.B. (Dublin), Charles
 Symonds, M.S., F.R.C.S., on August 2nd.

The following papers have been announced:
 BRONNER, A. M.D. (Bradford). Some cases of Diseases of the Larynx and
 trachea treated by intralaryngeal injections.

HODGKINSON, Alexander, M.D. (Manchester). (1) A new form of Mag-
 netic Laryngoscope. (2) On the Vibrations of the Vocal Cord. (3) On
 the Function of the Laryngeal Ventricles.
 INTERMITH, C. R., M.D. (Glasgow). Some points in the Anatomy and
 Physiology of the Larynx.

MACINTYRE, J. M.B. (Glasgow). On the Demonstration of a new
 powerful and extremely portable Electric Light Battery, as a
 powerful Electric Light Laryngoscope.

SPENCER, J. M.D. (Manchester). Vocal Polyps among School
 Boys, with special reference to the occurrence of teachers' voices.

WAGGETT, E. M.D. (Manchester). (1) The Laryngeal Symptoms and
 signs of Inflammation. (2) A new method of Laryngoscopy.

WAGGETT, E. M.D. (Manchester). The Importance of Adenoid of the
 Velum in the Etiology of the Larynx.

DE HAVILLAND HALL, F.R.C.S. The Operation of Thyroidectomy with a short
 account of the cases in which it has been performed at St. Bartholomew's
 Hospital during the last fifteen years.

STOKER, George, M.R.C.P. An improved method of removing Nasopharyngeal Tumours.

part in the work of the Section: Professor Fraenkel, Professor
 Guye, Dr. Luc, Dr. Bryson Delavan, Professor Moritz
 Schmidt (Frankfurt), Dr. F. H. Bosworth (New York), Dr.
 John Mackenzie (Baltimore), Professor v. Sokolowski (War-
 saw), Dr. A. Brady (Sydney, N.S.W.), Dr. Walker Downie
 (Glasgow), Dr. Hillis (Dublin), Dr. W. Robertson (Newcastle-
 on-Tyne), Dr. Cecil Shaw (Belfast), Dr. W. Bolton Tomson
 (Luton), Mr. R. Stow Armstrong, and Dr. Dmochowski
 (Warsaw), Dr. Logan Turner (Edinburgh).

N. DERMATOLOGY.

West Wing Room, Second Floor—Conjoint Examination Hall.

President: H. RADCLIFFE CROCKER, M.D. Vice-Presidents:
 McCALL ANDERSON, M.D.; MALCOLM MORRIS, F.R.C.S. Edin.;
 J. J. PRINGLE, M.B.; WM. ANDERSON, F.R.C.S.; H. A.
 G. BROOKE, M.B. Honorary Secretaries: J. HENBURY
 STOWERS, M.D., 41, Pinbury Square, E.C.; JONATHAN
 HUTCHINSON, Jun., F.R.C.S., 15, Cavendish Square, W.
 Wednesday, July 31st, 10 A.M. President's Address.

The following subjects have been selected for discussion in
 the Section:

The Pathology and Treatment of Pruritus, introduced by
 McCall Anderson, M.D., of Glasgow, and H. A. G. Brooke,
 M.B., of Manchester.

Diet in the Etiology and Treatment of the Diseases of the
 Skin, introduced by W. Allan Jamieson, M.D., of Edinburgh,
 and Walter G. Smith, M.D., of Dublin.

The following papers have been announced:

ANDERSON, William, F.R.C.S. The Treatment of Adenoma Sebaceum.
 COTTERELL, Edward, F.R.C.S. The Treatment of Syphilis by Injections
 of Syphilitic Antitoxin.

DAVIS, Arthur T., M.D. A Case of Lupus; Result of Treatment by
 Thyroid Feeding (with Photographs).

EDDOWS, Alfred, M.D. Brief Notes on Corns—true and so-called (Draw-
 ings and Microscopic Specimens).

FOX, T. Colcott, M.B. Two Short Papers.

GALLOWAY, James, M.D. Certain Nervous Lesions of the Skin.

HARRISON, A. J., M.B. On Two Cases of Unusual Verruca Neovascularis
 (with Photographs).

HUTCHINSON, Jonathan, Jun., F.R.C.S. Microscopic Sections, and Draw-
 ings of Case of Rodent Ulcer of Forearm.

LIDDELL, John, M.D. (Warwick). Case of Pityriasis Rubra Pilaris.
 Clinical Features, and Microscopic Anatomy (with Microscopic Sections).

MACKAY, Edward, M.D. (Brighton). Cheilo-pompholyx in association
 with Eczema.

MANSON, P. M.D. Short Communication on the Guinea Worm (with
 Microphotographs).

PERMIT, George, L.R.C.P., M.R.C.S. Pemphigus.

PYE-SMITH, P. H., M.D., F.R.S. Affections of the Skin occurring in the
 Course of Bright's Disease.

ROBERTS, Leslie, M.D. Treatment and Prognosis of Trichophyctosis based
 on the Physiology of the Pathogenic Fungus.

SMITH, Gilbert, F.R.C.S. Edin. (Birmingham). Note on a Case of Lichen
 Planus Verrucosus.

STANTIN, James, M.R.C.S. One or Two Living Specimens of Uncommon
 Eruptions, and Short Notes.

STOKER, George, M.R.C.P. The Treatment of Alopecia Areata by Oxygen
 Gas.

STOWERS, J. Herbert, M.D. On a Case of Dermatitis Erythema (with Coloured
 Drawings).

WATSON, Henry, M.D. (Glasgow). Paper on Alopecia Areata.

WALKER, Norman, M.D. (Edinburgh). The Methods of Examination of
 the Skin Histologically.

Friday, August 2nd, will be devoted to the demonstration
 of cases. Notice should be sent by members intending to
 exhibit, with description of cases to J. H. Stowers, M.D., not
 later than July 27th.

O. ERNICE.

Room B—King's College.

President: W. E. CHEVRELAND, M.D. Vice-Presidents:
 THOMAS BRIDGWATER, M.B.; J. HUGHES HEMMING, M.R.C.S.;
 D. H. BATHURST, F.R.C.S.; C. PARSONS, M.D.; W. H. ASHFORD,
 M.B.; A. DEMPSEY, M.D. Honorary Secretaries: MAJOR
 GREENWOOD, M.D., LL.B., 244 Hackney Road, N.E.; T. F.
 FRASER, M.D., 12, Norfolk Street, Southsea; HERB WOODS,
 M.D., 11, Archway Road, Highgate, N.

Wednesday, July 31st.—General Address by the President.
 Subjects concerning more particularly the relations of medi-
 cal men with each other:

1. Intra-professional Etiquette, introduced by Thomas
 Garrett Horder, L.R.O.P.

2. Advertising, introduced by George Wm. Potter, M.D.

3. Unqualified Assistants, introduced by George Benson,
 M.R.C.S., and continued by J. Brindley James, L.R.C.P.

Thursday, August 1st.—The Ethics of Gratuitous and
 Cheap Contract Practice.

1. Clubs, Medical Aid Societies, and Contract Practice; introduced by R. W. Doyno, F.R.C.S. The discussion will be continued by Hughes Hemming, M.R.C.S., W. Gense, L.R.C.P., W. A. Elliston, M.D., A. H. Bampton, M.D., W. Newman, M.D., Philip Lee, L.R.C.P.I., and others.

2. Hospitals and Dispensaries, introduced by Hugh Woods, M.D. Frank Greaves, M.R.C.S., R. R. Rentoul, M.D., and Nelson Hardy, F.R.C.S., will take part in the discussion.

The Secretaries will be glad to hear from members willing to join in the above discussions.

Friday, August 2nd.—1. Any subject, the discussion of which has not been completed on the two previous days.

2. The reading of any selected papers which do not come under the above heads.

The following papers have been announced:

BERRY, Wm., F.R.C.S. On Contract, Club, and Dispensary Practice.
BLACK, D. Campbell, M.D. On Hospitals Advertising and Medical Etiquette.

DICKINSON, W. G., L.R.C.P. Provident Principle in Sickness Attendance.
GORDON, J. Grierison, M.B., Barrister-at-Law. Medical Polity.

MOLLING, George Lang, M.D. On the Profession in New South Wales.
FRANK, T. F., M.D. The Breaching of the Profession by Various Friendly

Rich, William Richardson, M.D. The Public Medical Service and its Relations to the Public.

SMITH, Knowles, M.D. State Aided & Voluntary Hospitals.

WILLIAMS, A. D., M.D. Changing Relations of the Profession and the Public.

Honorary Local Secretaries:

ANDREW CLARK, F.R.C.S., 71, Harley Street, W.

ISAMBARD OWEN, M.D., 40, Curzon Street, W.

Honorary Local Treasurer:

GEORGE EASTES, M.B., F.R.C.S., 35, Gloucester Terrace, Hyde Park, W.

PROGRAMME OF PROCEEDINGS.

TUESDAY, JULY 30TH, 1895.

9.30 A.M.—Meeting of 1894-95 Council. Council Room, Exeter Hall.

11.30 A.M.—Special Service at St. Paul's Cathedral. Sermon by the Most Rev. His Grace the Lord Archbishop of Canterbury.

2.30 P.M.—First General Meeting. Report of Council. Reports of Committees, and other business. Exeter Hall.

8.30 P.M.—Reception by the Metropolitan Counties Branch.

9 P.M.—General Meeting. President's Address. } In the Imperial Institute

9.45 P.M.—Conversations.

WEDNESDAY, JULY 31ST, 1895.

9.30 A.M.—Meeting of 1894-95 Council. Council Room, Exeter Hall.

10 A.M. to 2 P.M.—Meetings of Sections. King's College, Conjoint Examination Hall, and Exeter Small Hall.

3 P.M.—Second General Meeting. Exeter Hall. Address in Medicine by Sir WILLIAM BURNARD, M.D., F.R.C.P., Physician-in-Ordinary to H.R.H. the Prince of Wales. Any business adjourned from First General Meeting at 2.30 previous day.

8.30 P.M.—Musical Promenade at Gardens of Royal Botanic Society.

8 P.M. to 12 P.M.—Illuminated Evening Fête at Gardens of Royal Botanic Society.

THURSDAY, AUGUST 1ST, 1895.

9.30 A.M.—Meeting of Council. Council Room, Exeter Hall.

10 A.M. to 2 P.M.—Meetings of Sections. King's College, Conjoint Examination Hall, and Exeter Small Hall.

3 P.M.—Third General Meeting. Exeter Hall. Address in Surgery by JONATHAN HUTCHINGS, F.R.S., F.R.C.S., Consulting Surgeon to the London Hospital. Presentation of the Stewart Prize to Brigade-Surgeon-Lieutenant-Colonel D. Douglas Cunningham, M.B., C.I.E., F.R.S.

7.50 P.M.—Dinner of the Association at Queen's Hall, Langham Place.

FRIDAY, AUGUST 2ND, 1895.

10 A.M. to 2 P.M.—Meetings of Sections. King's College, Conjoint Examination Hall, and Exeter Small Hall.

3 P.M.—Concluding General Meeting. Exeter Hall. Address in Physiology by EDWARD ALBERT SCHAFER, F.R.S., Jodrell Professor of Physiology, University College.

9 P.M.—Conversations at the Royal College of Physicians.

9 P.M.—Conversations at the Royal College of Surgeons.

SATURDAY, AUGUST 3RD, 1895.

ENTERTAINMENTS.

Particulars of further Entertainments, open to a limited number of Members only, will be found in the Local Guide.

RECEPTION ROOM

The large hall at King's College will be opened at 12 o'clock noon on Monday, July 30th, and on Tuesday, July 31st, and the following days at 9 o'clock, for the issue of tickets to members and for supplying all necessary information. A reception room for invited foreign guests will be provided next to the large hall. It is particularly requested that members on their

arrival will at once proceed to the reception room, King's College, enter their names and addresses, and obtain their tickets and Daily Journals containing programme, inquire for letters and telegrams, consult the list of lodgings, hotels, etc.

HOTEL ACCOMMODATION AND LODGINGS.

A list of hotels offering special tariffs or discounts on their tariffs, together with a list of apartments which are recommended by members of the Association, may be had on application to the Honorary Secretary of the Reception Committee, 11, Chandos Street.

Only members of the British Medical Association, invited guests and accredited strangers will be allowed to attend the general meetings or the meetings of sections. Members and guests will be required to show their cards, which must be obtained and signed for at the Reception Room. Invited guests will be required to show their invitation cards upon entrance to any of the general meetings or meetings of sections. Members and guests are therefore earnestly enjoined to take care of their cards of admission, and to note that they are not transferable, and if lost cannot be renewed. Members or guests may take one lady only to any of the entertainments.

Only members and officially invited guests will be admitted to the dinner of the Association.

The Reception Rooms will be opened on Monday, July 30th, at 12 o'clock noon. Tickets for the dinner and excursions will not be issued until Tuesday morning. In applying for tickets members will be required to produce their membership cards to be stamped.

The members' Reception Room is in the large hall of King's College. There is a separate Reception Room for invited foreign guests next to the members' Reception Room, and another for ladies at the Royal Society's Rooms, Burlington House.

The post office and telegraph office are in the Reception Room, King's College. Members are requested to apply for letters and telegrams from time to time.

Members of the Association who intend visiting London during the annual meeting to be held on July 30th, 31st, August 1st and 2nd, and who have not already sent in their names, are particularly requested to fill up the form in the centre of last week's JOURNAL, and to stamp and post it, in order that the arrangements may be completed.

NOTICES OF MOTION.

DR. ARTHUR WELSFORD hereby gives notice that he will move and Mr. J. E. BULLAR will second:

That it is to the interest of the public and of the medical profession that the Council of the British Medical Association should take power and authority to protect both the individual and collective interests of the medical profession, and that the Council be requested to take such steps as may be necessary to enable it to actively undertake these duties.

MR. LAWSON TAIT hereby gives notice that he will move, and Mr. COLIN CAMPBELL will second:

That we, the members of the British Medical Association, while anxious to improve the training and supervision, and, if need be, to support, a practical scheme for the registration of medical, surgical and midwifery nurses, emphatically condemn any proposal which has for its object the formation of a class of medical or surgical or midwifery practitioners other than those recognised under the Medical Act, 1886, as now existing. We protest against the Midwives Registration Bill because it proposes to establish a class of midwifery practitioners who would be very incompletely trained in midwifery, and entirely uninstructed in medicine, surgery, and pharmacy—a matter of supreme importance in midwifery practice. We therefore instruct the Council and the Parliamentary Bills Committee to use every means to oppose any Bill which proposes to give to persons registered under it power to conduct, on their sole and independent responsibility, any midwifery practice without the guarantee of a complete curriculum and qualification. That this Association recommends a sum not exceeding £1,000 be expended for the purpose of opposing any such Bill.

DR. INCH hereby gives notice that he will move as an amendment to the above:

That in the interests of the mothers of the United Kingdom the registration of midwives, after suitable training and examination, is a subject deserving the early and careful consideration of the Legislature, and that consideration it is equally desirable that the legitimate rights and privileges of duly qualified medical practitioners should not be overlooked.

DR. BEDFORD FENWICK hereby gives notice that he will move:

That in the opinion of this meeting it is expedient that an Act of Parliament should, as soon as possible, be passed providing for the registration and education of medical, surgical, and osteopathic nurses; and the Council of this Association are therefore requested to consider this matter, and to take such measures as may seem to them advisable to obtain such legislation.

PROPOSED INCREASE IN THE NUMBER OF DIRECT REPRESENTATIVES ON THE GENERAL MEDICAL COUNCIL.—Dr. R. R. KENTON, hereby gives notice that he will move, and Dr. H. Woods will second:

That as Sections 7 and 8 of the Medical Act, 1886, provide for the election of only five direct representatives to the General Medical Council by the registered medical practitioners resident in the United Kingdom; and as Section 10, Sub-section 1, Paragraph c of this Act provides that the General Medical Council may represent to the Privy Council that it is expedient to confer upon the registered medical practitioners resident in any part of the United Kingdom the power of returning an additional number of direct representatives to the General Medical Council; and as the General Medical Council has, on November, 1890, on November, 1891, and on November, 1892, refused absolutely to make such representation; and as the number of registered medical practitioners has increased from 22,718 in 1886 to 28,000 in 1891; and as no medical practitioners were not given our due and proper number of direct representatives in 1886; and as the registered practitioners contribute all the income of the General Medical Council, by which the Medical Acts are administered, while the twenty universities and colleges represented on the General Medical Council do not contribute any income to it; and as the representatives of the universities and colleges are elected to the General Medical Council for their small Convocations, Senates, and Councils, and not by open vote of all their medical graduates only; and as other important councils, having similar but larger duties to the General Medical Council, such as the Councils of the Incorporated Law Societies of England and of Ireland, the Councils of the Pharmaceutical Societies of Great Britain and of Ireland, and the Council of Veterinary Surgeons, consist of direct representatives only, this Association instructs its Council to take immediate steps to have a Bill introduced into Parliament providing that the registered medical practitioners in England and Wales be empowered to elect five additional direct representatives, the practitioners resident in Scotland one additional direct representative, and the practitioners resident in Ireland one additional direct representative to the General Medical Council.

Dr. BEDFORD FENWICK hereby gives notice that he will move:

That, in the opinion of this meeting, the time has arrived when it is expedient that the registered medical practitioners resident in England, and also the registered medical practitioners resident in Wales, should separately be granted the privilege of returning one additional member to the General Medical Council; and the Council of this Association are therefore requested to petition the General Medical Council to represent to Her Majesty's Privy Council the expediency of such an addition to their members, in accordance with Section 10 of the Medical Act of 1886.

THE UNRESTRICTED SALE OF POISONS AND OTHER DANGEROUS DRUGS BY CHEMISTS BY MEANS OF PRESCRIPTIONS OF MEDICAL PRACTITIONERS.—It will be moved by Dr. R. R. KENTON:

That owing to the unrestricted dispensing by chemists of prescriptions of medical practitioners on more than one occasion which contain poisons and other dangerous drugs, having regard to the evils arising therefrom, and following the law in other countries, this Association recommends its members to write across the face of such prescriptions the words, "Not to be repeated," or "To be repeated once," and "To be repeated by the chemist to the practitioner," duly stamped and dated. And that if chemists refuse to adopt this rule, the members residing in cities and towns are recommended to establish, own, and manage under their exclusive control depots at which all their prescriptions shall be dispensed.

PROPOSED FUND FOR THE BENEFIT OF THE WIDOWS AND ORPHANS OF MEDICAL PRACTITIONERS.—It will be moved by Dr. R. R. KENTON:

That this meeting instruct the Council to obtain a table from an actuary showing the amount of annual and other payments necessary to provide the widows and orphans of subscribers (as their right and not as a charity) with an annuity of £50 or any multiple of £50 not exceeding £200. That such fund consist of two departments: First, an annuity department, the payments to which shall consist of entrance tax, marriage tax, age tax, husband and wife separating age tax, annual tax, and foreign residents tax. No annuity to go to the widow so long as she remains a widow, and on the death of the widow, or on the death of the subscriber, and leaving a widow to the male and female children the name of the subscriber, until the youngest male child has attained the age of 18 and unmarried, or the youngest female child the age of 21 and unmarried. Secondly, an immediate benefit department, to be based upon the principle of having no annual fees, but an agreement made by each subscriber who is a member of the annuity department to pay a small sum of money on the case according to the death of each subscriber. The death of the subscriber is to be notified to the General Secretary, who shall give notice to the next issue of the *British Medical Journal* of the death and shall upon each week thereafter to contribute the amount of call. Subscribers of this department, whether married, single, or widowers, to receive the power to be granted the proceeds of such "call" either to their widow, children, parents, or other nominees. That Mr. James Chatham, F.R.S., Edinburgh, who has advised Dr. Kenton regarding the formation of such a medical practitioners' widows' and orphans' fund, be requested to draw up the above-mentioned table.

PROPOSED IMPROVEMENT IN THE TRAINING OF MEDICAL STUDENTS IN PRACTICAL MIDWIFERY.—It will be moved by Dr. LOVELL DRAGE:

That we view with deep concern and regret the recommendation of the General Medical Council to the effect that every student who presents a certificate stating that they have "conducted personally" only three and "been present at" only three confinements, but at the General Medical Council has refused to accept the recommendation, and we instruct our Council to petition the General Medical Council to recommend that no student be admitted to his final medical examination until he presents a certificate showing that he has personally conducted at least thirty confinements under the direct supervision of a registered medical practitioner. We also instruct the Council to take immediate steps to have Section 20 of the Metropolitan Poor Act, 1867, repealed, which prevents workhouse infirmaries from being used for the clinical instruction of medical students in practical midwifery. We also instruct the Council to petition the Government, the Local Authorities, the British Lying-in, and the Lying-in Maternity to withdraw their rule which excludes male medical students from clinical instruction at these hospitals, seeing that these are now used by pupil midwives.

June, 1905.

FRANCIS FOWKE, General Secretary.

The Ladies' Reception Committee have organised the following excursions, under the guidance of experts, for the benefit mainly of the wives of members of the Association. Should any lady, however, wish to obtain a ticket for an excursion for her husband it will be possible for her to do so. The number of tickets for each excursion will be strictly limited, and it is mentioned below. The cost of a ticket for each excursion, except for the one to the Cambridge Colleges, will be 1s. Ladies living in London will not be able to obtain tickets till the week of the meeting. Ladies living in the country or abroad may obtain them in advance by writing, and enclosing postal orders, to Mrs. R. Priestley, 81, Linden Gardens, Bayswater, London, W.

1. Giron and Newnham Colleges, Cambridge (40 tickets). The party will be entertained at the two Colleges. Date: Friday, August 2nd.

2. Westfield College, Hampstead (30 tickets). Date: Friday, August 2nd. Tea and coffee will be provided by the College.

3. British Museum. Mr. A. S. Murray will take a party of 15 on two days to the Greek antiquities, and Mrs. Tirard will take a party of 15 on one day to the Egyptian antiquities.

4. St. Paul's Cathedral. The Rev. Canon Gilbertson will take a party of 30 on July 31st.

5. Westminster Abbey. The Very Rev. the Dean of Westminster, Mrs. Murray Smith, and Mr. Weller will respectively take a party of 30 on July 31st, August 1st, and August 2nd. The Royal and other wax effigies in the Abbey will be shown.

6. The Tower of London. The Rev. W. J. Loftie will take a party of 25 on July 31st at 2 p.m. Special orders have been obtained from the Governor of the Tower.

7. National Gallery. Mr. Cosmo Monkhouse and Miss M. K. Bradby will take a party of 12 on July 31st and August 1st respectively.

8. Natural History Museum. Mr. George Murray will take a party of 30 on July 31st at 11.30 a.m.

9. South Kensington Museum. The Director, Mr. Armstrong, will take a party of 12 on July 31st and August 1st, at 2.30 p.m.

SPECIAL CORRESPONDENCE.

PARIS.

Alcoholism and its Remedies. Death from Roux's Serum. Acetic Acid in Fainting Fits. Coffee Adulteration. "Le Secret Professionnel" and Law Proceedings. Medical Examination Analysis. The President's Visit to the Hôtel Dieu Hospital. General News.

At a recent meeting of the Paris Academy of Medicine, M. Rochard declared that the first step to take to combat the increase in alcoholism and its terrible results is the suppression of inferior *can de vin*, and of the artificial "bouquet" used in making up wines and spirits. This result, M. Rochard believes, can only be attained by the State assuming the right and responsibility of "rectifying" alcoholic drinks, though ethyl alcohol is a poison even when pure. During the last twenty years the quantity of alcoholic beverages con-

summed has been doubled. The number of insane from alcoholism has increased to such an extent that the municipal council has voted funds to create at Ville Evard an asylum for the insane capable of containing 500 men and 200 women. M. Laborde suggested that the number of wine-shops should be limited. M. Rochard considered that the law of 1865, which forbade wine shops to be opened without an authorisation from Government, should be reinstated. In 1871 this law fell into abeyance, and since then the number of wine shops has increased to a terrible extent. A wine shop can be closed if drunkenness takes place in it, but this law is not enforced. M. Lagneau, the eminent statistician, stated that the principal causes of degeneration and destruction among the French population were tuberculosis and alcoholism. At Rouen and Havre, where the yearly average consumption of alcohol is 14 litres a head, there are 402 and 502 deaths yearly from phthisis in a population of 100,000; whereas at Toulon, where the consumption is at the rate of 2 litres, the mortality from phthisis is 200. Alcoholism is an important factor in the increased death-rate from phthisis among men compared to that among women. At Paris in 1890 there were 29,583 wine shops, that is at the rate of one in every three houses, or 82 inhabitants. M. Lagneau suggests to increase the price of their licence and to impose heavy taxes on all such shops. M. Motet declared that drunkenness nowadays is much more serious in its results. This affirmation is confirmed by a mother, who said to M. Motet: "When my husband was drunk he was only troublesome, but now when my son is drunk I am frightened of him, he is like a madman." The Bill which has been passed in the French Parliament relieving the *boisson hygiéniques* of taxes and giving the State the monopoly of alcohol rectification is only an apparent remedy. The law is not yet formulated, and many difficulties remain to be grappled with.

At a recent meeting of the Société Médicale des Hôpitaux M. Morzard read notes on a case of death which resulted from the injection of Roux's serum in the case of a child who was not attacked by diphtheria. Dr. Sevestre, Dr. Legendre, and Dr. Variot have observed and commented on the serious disturbance caused by serum injections. Paralysis has been observed in some instances, also cerebral trouble and diminished urinary secretion, but all the children thus affected were cured. MM. L. Guinon and Roufflange were the first to notify a case of death from serum injections.

The *Annales d'Hygiène et de Médecine Légale* draws attention to the practice of using acetic acid to restore consciousness in swoons. Dr. Langier has pointed out that if the inhalations are continued for too long a time inflammation of the pituitary membrane may result; further, the patient whilst struggling may jerk the bottle and cause some drops to fall on the skin. Dr. Langier mentions two such cases resulting in legal proceedings taken against the medical men who treated the patients.

M. Ch. Girard and M. Dupré, of the Paris Municipal Laboratory, have described some of the manifold adulterations to which coffee is subjected. In ground coffee, they detected several plants better absent than present, in order to assure a good "coloration" to this detestable compound. "Floor sweepings" are mixed with it. Whole coffee is adulterated by soaking it in water; thus the weight is increased. During the roasting process fatty substances are added, and eggs or treacle; the beans thus present a shiny surface. The adepts even fabricate coffee beans with coffee grounds and burnt flour.

A curious case of failure to observe the *secret professionnel* has figured in the Paris law courts. Dr. Catuffe, at the request of M. Bertrand, an architect, attended a lady during her confinement. M. Bertrand showed no desire to pay the fees justly claimed by Dr. Catuffe, who wrote to the lady in question in order to receive his remuneration, and stated that otherwise he should take proceedings. No answer being returned, Dr. Catuffe was as good as his word. His fees, amounting to £16 15s., were reduced to £12, and M. Bertrand in his turn took proceedings against Dr. Catuffe for violation of the professional secret. Dr. Catuffe lost the day, and is fined £12.

Dr. Lemoine, of Lille, has used methylene blue as an analgesic with great success in neuralgia, sciatica, and locomotor ataxy. He gives 30 centigrammes a day.

The President of the Republic has visited the Hôtel Dieu Hospital, and as usual has expressed his entire satisfaction. Before leaving, he presented M. Tillaux, the well-known surgeon, with the Cross of Commander of the Legion of Honour, the Cross of Officer to M. Nicolson, surgeon at the Laennec Hospital, and M. Constantin Paul, of the Chante Hospital; that of Chevalier to M. Delens, surgeon at the Lariboisière Hospital, and M. Kirmisson, surgeon at the "Enfants Assistés." The President also distributed eight medals among the staff of nursing attendants, male and female.

During the last few days several animals have been bitten by vipers in the Haute Vienne department, they were treated with chronic acid injections and recovered.

A fine of eleven francs has been inflicted by a Paris law court on somnambulists for professing to interpret dreams and prophesy future events.

M. Louis André Anastay, the father of the murderer of the Baroness de la Cour, has been sentenced to imprisonment and fined for illegally practising medicine; he gives consultations on specific disorders.

The fête given at Lyons for the benefit of the Madagascarese Ambulance has realised £780.

M. Paul Reclus has been elected member of the Paris Academy of Medicine.

The death is announced of Octave Doyen, Mayor of Rheims. Chevalier of the Legion of Honour, Municipal Councillor, and father of M. Eugène Doyen, the well-known surgeon.

ROME.

Infectious Diseases in Italy.—Unhealthy Industries.—A Society for the Protection of Children.—The Milk Supply of Rome.—General News.

THE Sanitary Act of 1888 compels medical practitioners throughout the kingdom to report all cases of infectious diseases they attend to the syndics of the various communes in which these diseases occur. The syndics are required by the same Act to send a monthly bulletin of those diseases to the Director of Public Health at the Ministry of the Interior. With the view of preventing any mistakes in the returns, the syndics are also obliged to send a blank form whenever they have no infectious diseases to report during the month. Notwithstanding these requirements, Dr. Pagliani states in his report on "Cases of Infectious Diseases reported by the Medical Attendants to the Syndics of the Communes in 1894," that although the reports are more complete than in previous years, yet he has to deplore many lacunae in the compilation of the bulletins. There are altogether 8,257 communes in Italy, and of these a monthly average of 1,283 have not sent in even a negative notice. It will be seen, therefore, that there is an element of doubt as to the following figures being complete:—In the year there were reported 7,894 cases of small-pox, 109,506 of measles, 18,482 of scarlatina, 37,260 of typhoid fever, 7 of typhus, 23,898 of diphtheria, 3,094 of puerperal fever, 2,400 of malignant pustule, 103 of hydrophobia, and 81,449 of influenza. Considering these diseases separately from the point of view of greatest and least monthly prevalence, it appears that small-pox was most prevalent in March, April, and May. April had the greatest number (1,207), least in December (408 cases); measles was most prevalent in March, April, May, and June, highest in April (16,657 cases), and lowest in October (3,457 cases); scarlet fever varied very little throughout the twelve months; the highest figures were in May (1,789 cases), and the lowest in February (1,172 cases); typhoid fever was most prevalent in August, September, and October, highest in September (6,442 cases), and lowest in February (1,226 cases); of the 7 cases of typhus reported, 5 occurred in September and the remaining 2 in October. It is strange that these cases occurred in different provinces, with the exception of 2 in Potenza; diphtheria was most prevalent the first and fourth quarters of the year; it was almost equally prevalent in April, September, and October, highest in November (2,352 cases), and lowest in June (1,383 cases); puerperal fever did not vary very much in different months; the highest was in March

(302 cases), and the lowest in August (313 cases); malignant pustule was most prevalent in August, September, and October, highest in September (497 cases), and lowest in April (77 cases); hydrophobia was most prevalent in May, July, August, and October, highest in August (15 cases), and lowest in April (2 cases); influenza was most prevalent in January, when 10,371 cases were reported; in February there were 27,881; there was a rapid fall each month until July, when it totally ceased until December, when there were 121 cases reported. Contrasting these figures with those of the six previous years, and taking into consideration the estimated increase of the population of the kingdom, there has been a gradual diminution in the number of cases reported in nearly all these diseases.

The Minister of the Interior has by decree approved of the list of unhealthy occupations compiled by the Superior Council of Health. The list is divided into two classes; it comprises in the first class those which must be isolated in the Campagna and at a distance from habitations; and in the second those which require special caution for the safety of the neighbourhood.

On June 7th the Queen of Italy received in private audience Senator Costa, Professor Pagliani (Director of Public Health), and Professor Blasì (Director of the Brevettorio), who presented Her Majesty with a volume entitled *Pro Infantia*, containing a collection of writings and drawings by the best Italian authors and artists on the protection of ill-nourished and badly-treated young children. This work is the first manifestation of a great association which is being founded, with its centre in Rome and branches in every town in Italy, for the purpose of uniting the scattered strength of the many philanthropic persons who interest themselves in this sad question. The Queen and also the King—to whom was presented a similar volume a few days before—are taking the greatest interest in the establishment of this new society, and have encouraged the promoters to carry on their good work by promising them all necessary support and their full protection.

For some time past excellent regulations have been in force in Rome proper in relation to the health of milch cows and other animals which supply milk to the residents. By an order of the syndic just issued similar regulations are put in force for the whole of the Commune, which includes a considerable extent of the surrounding Campagna. They are to the following effect: All milch cows and other animals which supply milk in the suburbs and Agro Romano will be subjected to a rigorous examination by the municipal veterinary surgeons. To this purpose notice of every animal introduced into the Commune must be given to the health authorities before the milk can be sold, and it is then placed under the inspection of the veterinary surgeon. When the animal is healthy and capable of furnishing good milk it will be marked in the horn, and a special licence will be given to the owner. These animals will be inspected every year, in the months of April, May, and June, and also on any other occasion that the authorities may deem necessary. The cows suspected of tuberculosis may be treated with tuberculin at the expense of the owners, and those diseased will be slaughtered. The extension of these regulations to the whole Commune is a great boon to the inhabitants, as now all the cows which supply milk to the city will be under inspection, and this will prevent the owners in Rome proper sending tuberculous cows into the Campagna, where they might continue to supply milk. The milk coming from the Campagna will be preferable, as it will be obtained from cows kept in the fields.

Professor Baccelli, Minister of Public Instruction, intends to introduce immediately to Parliament, which opened on June 10th, his Bill entitled "Autonomia Delattico Amministrativa Dispendio Università."

Dr. Toscani, Professor of Legal Medicine in the University of Rome, has been re-elected President, for three years, of the Medico-Chirurgical Faculty of the University. This is the fourth time the Professor has been elected.

Professor Durante has been elected a foreign member of the Academy of Medicine of Paris, Surgical Section.

Mr. Jankz Hoon has received a Civil List pension of £75 a year for his contributions to medical science.

MELBOURNE.

Decrease in the Population of Victoria.—Tuberculosis in Cattle.—The Feeding of Troops on Active Service.—The Consumption of Sugar in Australia.—Overworking of Nurses.—A Medical Legal Sensation.—The Female Medical Students at the University.—General News.

THE population of Victoria has decreased by 40,000 during the last three years. The net loss by emigration for one year was nearly 14,000. In the year 1891 the population of Victoria was 1,173,104, while that of New South Wales was 1,261,480.

The prevalence of tuberculosis among man in Victoria has directed attention to the subject of tuberculosis in cattle, and the danger to children in the consumption of milk from tuberculous cows. An effort is now being made, thanks to a persistent agitation on the part of Dr. J. J. Miller, to compel the Government to arrange for a regular veterinary inspection of dairy herds. An attempt is also being made to induce the various municipalities to undertake the work themselves. In Queensland, out of a herd of 150 cattle taken from off the best grazing grounds, only 25 head were found free from tuberculosis.

At a special meeting of the Naval and Military Club, and in the presence of the commandant and principal officers of the forces, Dr. Miller delivered a most instructive lecture on the means of examining meat, and detecting its unwholesomeness while either in the field or in garrison. In the discussion which followed Dr. Henry indicated the importance of the selection of suitable food stuffs previous to an engagement in active campaigning. He declared that the efficiency of the troops to withstand a struggle would be better maintained by the indulgence in food which contained nothing fermentable. For this reason saccharine and starchy food should be avoided, inasmuch as they inclined to produce a condition favouring lethargy and loss of activity.

The amount of sugar consumed by each head of the population of Victoria is calculated at 90.75 lbs. per annum. South Australia consumes 102.10 lbs. per head per annum, Western Australia 93.61, Tasmania 90.49, New Zealand 87.18, Queensland 62.93, New South Wales 60.93 lbs. per head per annum. For the rest of the world the figures are, for comparison sake: United Kingdom 68.99, United States of America 48, Holland 28.37, France 22.66, Germany 15.01, Austria 3.98, Russia 7.69, Spain 5.11, and Italy 3.20. The explanation of the excessive quantity partaken of in Australia is attributed to the tea drinking tastes of the people, whereas in wine-drinking countries very little sugar is consumed. Here people are also great jam eaters and beer drinkers. So far statistics of diseases said to be caused by sugar feeding have not been tabulated.

Attention has been recently directed to the excessive duties which hospital nurses are called upon to fulfil. It has been shown that in many instances a nurse's duties extend uninterruptedly for fifteen hours. As the nurses themselves exhibit a good deal of diffidence in pleading their own cause, the matter of relief remains in abeyance.

The present medico-legal sensation is a strychnine-arsenic poisoning case. A Mrs. Dean, living in Sydney, accuses her husband, who is a man who has hitherto borne a remarkably good reputation, of attempting to poison her. At the trial the judge, in charging the jury, declared the evidence of poisoning to be to his mind as clear as if he had seen the prisoner place the poison in the food. The prisoner, who asserted his innocence throughout, was condemned to death, which sentence was afterwards commuted to imprisonment for life. In connection with this case some rather startling disclosures are promised, and a Royal Commission is being demanded to have the whole of the case reopened. It is stated, for instance, that there is no evidence except that of Mrs. Dean that her husband was seen to put poison in her food; that the medical evidence as to the symptoms being that of poisoning was merely based on the description of the symptoms by Mrs. Dean and her mother; that the doctor did not attend Mrs. Dean while she was suffering from these symptoms; that there was no direct evidence that the poison was ever in Mrs. Dean's body; that the only poison found was in the excreta and in remnants of unconsumed food; that there was

no scientific evidence to show that the poison in the excreta had ever passed through the body; that the quantity of poison in the excreta was so great as to make it improbable that it could have passed through a human body without causing death.

The female medical students of our University have appealed to the Council against the decision of the medical faculty in compelling them to occupy a joint dissecting room with the male students. The Council has supported the objection of the ladies, and have directed that in future a separate room shall be provided for them.

Mr. F. D. Bird, Honorary Surgeon to the Melbourne Hospital, has been appointed lecturer on surgery at the Melbourne University.

Dr. T. Rowan, who is now on a visit to Europe, is a gentleman occupying one of the most distinguished positions in the profession in Melbourne. For many years he has been the senior surgeon to the Women's Hospital, and he is regarded as one of the leading representatives and exponents of this special branch of surgery in this colony. Such attention as may be shown to Dr. Rowan on his visit to the old country will be warmly appreciated by his professional brethren in this part of the world.

CORRESPONDENCE.

THE WEBER-PARKES PRIZE AND MEDALS.

SIR,—I should be grateful if you could find space in your columns for the following particulars respecting Dr. Hermann Weber's Prize Foundation at this College, which have not hitherto been made public.

The prize is of the value of £150 or thereabouts, to be awarded triennially to the author of the best essay upon some branch of the subject of tuberculosis, especially with reference to pulmonary consumption in man.

The first award will be made in 1897. The adjudicators have selected the following as the subject for competition in that year: "The Means, Prophylactic or Curative, deemed by the Author to have Value in the Control of Tuberculosis; especial regard being had to their application to Human Tuberculosis."

The essay must be based on original work and observations (experimental or other) of the author, and must include a detailed exposition of the methods employed and their mode of application.

The competing essays must be delivered to the Registrar of the College on or before July 1st, 1897.

I enclose the regulations printed in full, of which copies may be had on application at the College.—I am, etc.,

EDW. LIVING,

Royal College of Physicians, S.W., July 16th.

Registrar.

ANTIVENOMOUS SERUM.

SIR,—As a sequel to the article published in the BRITISH MEDICAL JOURNAL of June 15th concerning the researches of Dr. Thomas Fraser about the immunity against the venom of snakes, researches which corroborate the results that I have myself made known in my statements published in the *Annales de l'Institut Pasteur* in May, 1894, and in April, 1895, also by several communications to the Académie des Sciences de Paris, I would be very much obliged to you to inform your readers that since last January I prepare, at the Institut Pasteur de Lille, antivenomous serums from both horse and ass. I have already sent numerous samples of this serum to be used in treatment of man in the British East Indies, in Australia, and in the West Indies, and I have always on hand doses at the disposal of doctors who may wish to try it. Each bottle has with it a paper of instructions as follows:

INSTRUCTIONS.

The antivenomous serum is serum taken from an ass or a horse immunised against venom of snakes. It will retain its effects if kept in as cool a place as possible, away from daylight and without taking the phial out of its box. At or above the temperature of 59° Cent.—125° Fahr.—the serum becomes inactive. Its preservation has been guaranteed by adding a very small quantity of camphor.

Preventive Power.—The preventive power of this serum is, at the least, of 10,000, that is, it is sufficient to inject rabbits preventively with a quantity of serum equal to 1/1000 of their weight to enable them to bear, one

hour afterwards, without their being intoxicated, a dose of 1 milligramme of dry venom of any species of venomous activity, said dose sufficient to kill proved rabbits in less than four hours.

Therapeutic Action.—If injected in sufficient quantity to persons bitten by snakes, the antivenomous serum will prevent the effects of the venom providing intoxication is not too far advanced. It must be injected as soon as possible after the bite. Generally its intervention is still very efficacious an hour and a-half after the bite with adults, who rarely die but three hours after the bite of the most dangerous species of snakes. The serum is active against the venom of all species of snakes existing in the ancient and new world. It has been experimented with the venoms of the cobra capella and *ferusenurus* of Asia, the *naja* *haja* and *haja* of Africa, the *coralins* of America, the *bothrops* of the West Indies, the varieties of *pseudocrotalus* and *hoplocephalus* of Australia, and the vipers of Europe. The dose to employ varies according to the species of the biting snake, the age of the person bitten, and the time of the intervention. Generally 10 cubic centimetres are sufficient for children under 10 years and 20 cubic centimetres for adults. However, when the venom comes from a very dangerous species, such as the cobra capella, the *naja* *haja*, the *coralins*, the *bothrops* of the West Indies, it will be prudent to make one single injection at first of a double dose.

Treatment of Venomous Bites.—The first precaution to take is to surround lightly the bitten limb as near as possible to the bite and between the latter and the trunk with a strip or handkerchief. The wound will have to be washed with a solution of hypochlorite of lime diluted to 1 gramme for 50 of water previously boiled, tilting between 9 lit. 500 to 1 lit. 500 of chlorine per 1,000 cubic centimetres. The dose of serum must be injected in the subcutaneous cellular tissue in the right or left side of the belly, and with the usual antiseptic precautions. Then, with the same syringe, 5 or 10 cubic centimetres of the solution of hypochlorite of lime will be injected altogether, but in the different parts surrounding the bite and in the passage of said bite. These injections are intended to destroy there the venom which has not yet been absorbed. From that time the strip can be taken away from the limb; the patient must be frictioned and coffee or tea be administered, and he be covered warmly so as to provoke an abundant perspiration. The administration of ammonia or alcohol must be avoided; it would only be injurious both to the patient and to the treatment by the serum. It is also unnecessary to cauterise the bitten limb either by red iron or chemical substances.

—I am, etc.,

D. A. CALMETTE,

Lille, July 12th.

Directeur de l'Institut Pasteur de Lille.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

SIR,—Referring to the letter from "A Governor" in the BRITISH MEDICAL JOURNAL of June 29th, page 1470, the objects for which the British Medical Association was founded and is carried on are strictly defined in the Memorandum and Articles of Association and By-laws of the Association. They are stated thus:

3. The objects for which the Association is established are the promotion of medical and the allied sciences, and the maintenance of the honour and the interests of the medical profession by the aid of all or any of the following:

- (a) Periodical meetings of the members of the Association, and of the medical profession generally, in different parts of the country.
- (b) By the publication of such information as may be thought desirable in the form of a periodical journal, which shall be the journal of the Association.
- (c) By the occasional publication of transactions or other papers.
- (d) By the grant of sums of money out of the funds of the Association for the promotion of the medical and the allied sciences in such manner as may from time to time be determined on.
- (e) And such other lawful things as are incidental or conducive to the attainment of the above objects.

It cannot be pretended that this includes the giving in charity; nor can it be alleged that the objects so set forth are yet so fully accomplished and so definitely terminated that a diversion of funds towards a quite alien though admirable purpose is logically justified or morally necessary. It is convenient and easy and satisfying to the conscience without drawing upon the pocket, to apply public funds in a sympathetic way, without too narrowly questioning the authority or the wisdom of such gifts. But are there not in every Branch calls for the prescribed use of surplus funds in protection of the dignity of the profession and the welfare of the individual members of the Branch in the suppression of illegal practice by quacks and prescribing chemists, in the formation of local unions and their vigorous organisation to oppose medical aid societies, to combine against club encroachments and underpayments? It has become here and there the fashion to suggest that something vaguely called "The Association" should do more in these directions. But it should be remembered that "The Association," apart from its Branches, is but *nominis umbra*—mainly a list of subscribers to a cheap and popular JOURNAL. The Council, which can meet but rarely and at distant intervals, is largely

a formal and administrative body, having important controlling duties in these matters, but deriving all its authority from the local Branches. It is in the Branches, which have personal contact, local knowledge of men and things, and leisure and occasion for really effective combinations, that this battle must be fought out; and the local surplus funds appear to be the first sources from whence the necessary outlay might be drawn. It is, from this point of view, not altogether inspiring to see the Branches inactive and asking for a Jupiter without putting their own shoulders to the wheel. Nor does the dissipation of these funds in doles seem altogether consistent with the duties and obligations of the Branches.—I am, etc.,

A BRANCH MEMBER.

"VARIETY IN DIET."

SIR.—In some recent remarks on "Variety in Diet" you refer to the condensing and sterilising of milk as an instance of a process of cooking which "may do much more harm to the nutritional value of our food than is explained by the mere change in its physical properties by destroying the antiscorbutic properties of milk." Now this statement raises a very wide question because, as a matter of fact, we eat very little raw food of any kind. In former years it used to be taught that raw milk was more digestible than boiled milk, and the latter was consequently tabooed in respect of its administration to infants. Modern researches having proved on irrefragable data that various infectious diseases are commonly spread directly by the use of infected milk, eminent authorities in matters hygienic have inculcated the paramount necessity of boiling milk before giving it to children. Bacteriological investigations have amply confirmed the conclusions arrived at by official inspectors and others, and one of the most important points elucidated by the Royal Commission on Tuberculosis was the dependence of infantile tuberculosis on the consumption of the milk of diseased animals. Under these circumstances the use of sterilised milk ought shortly to become universal, and the objection to the use of condensed milk falls to the ground.

For uniformity of composition and richness in the essential constituents of normal milk condensed milk of good brand is far and away superior to ordinary milk, or to any of the so-called sterilised milks. The great point to which I desire to call attention is, however, the principle of using only sterilised milk. If this be desirable (and eminent authorities assure us that it is so), then no more satisfactory guarantee of sterility can be provided than by the process of condensation in which the cooking is not carried beyond the point at which sterilisation is ensured.

This is a matter of such immense importance to a community in which condensed milk is so largely used, that no apology is needed for having called attention to what seems to me to be an illogical and unjust criticism.—I am, etc.,

Gower Street, W.C., July 16th.

A. S. GUBB, M.D.

THYROID EXTRACT IN UNIVERSAL ALOPECIA.

SIR.—In the *BRITISH MEDICAL JOURNAL* of July 13th Sir Hugh Beaver briefly reports a case of universal alopecia treated with thyroid extract, and concludes by saying that even so small an amount of success in an ailment considered incurable makes this treatment worthy of further trial. May I be allowed to repeat what I have stated previously elsewhere, that I have given the thyroid treatment a full trial in both universal and partial alopecia, and have been unable to observe any beneficial effect therefrom. The remarkable results of the thyroid treatment in curing the baldness of myxedema at once suggested to me, as no doubt it did to others, a trial of the same treatment in baldness due to other causes. This treatment I carried out in a number of cases between two and three years ago. I had the patients photographed at the commencement of the treatment in the hope, which was disappointed, that I might have some improvement to show at the end.

Although universal alopecia is generally incurable it is not always so. I have seen two cases where the malady has been recovered from, apparently quite independent of treatment. In such exceptional cases had the thyroid gland or pituitary body been administered an altogether erroneous conclusion might have been deduced.

At the present day suggestions as to possible means of remedies which are being boomed by manufacturing chemists have to be made with great caution. These suggestions, often made with the best intentions, are sometimes reproduced in the advertising columns as reasons why these remedies should be used for quite inappropriate purposes and in diseases in which experience has already shown that they are of no value.—I am, etc.,

Weibek Street, W., July 15th.

HECTOR W. G. MACKENZIE.

THE LATE PLAGUE IN HONG KONG.

SIR.—As you are aware this colony last year was attacked by a virulent form of epidemic, that is, the bubonic plague. To describe the chaos and perturbation that existed in all circles—official, social, and military—would require a power of word painting of which I am not capable; suffice it to say that chaos existed, and with that chaos the accompanying bickering, backbiting, and thrusting of responsibility on the shoulders of those who had the pluck to take it. The fight is now over, and the spoils in the shape of honours and rewards you would imagine would go to those who had so manfully fought the battle. I am not concerned in the matter as to the rewards or wants of rewards that fell or otherwise to other departments, but will confine myself to the Colonial Medical Department, and more especially to the work done by the Acting Superintendent of the Civil Hospital. On his shoulders were thrown the organisation of all the plague hospitals, and it was by his heroic efforts and devoted zeal in spite of great opposition that they were efficiently equipped and maintained. This is no personal tribute to his ability and pluck, but a tribute that by common consent is paid him by all who were here in this anxious period. C.M.G.s, presentation inkstands, cheques, and commendations have been flying round, but the Colonial Medical Department, as represented by the Acting Superintendent, Civil Hospital, has not yet received any recognition of his efforts. The recognition by public opinion here and of his professional brethren at home will, I am sure, be considered by this officer of more value than any decoration that could be conferred by the Colonial Government, but it is nevertheless another gross instance of neglecting the claims of the medical profession.—I am, etc.,

Hong Kong, June 15th.

FIAT JUSTITIA RUAT CÆLUM.

THE SOCIETY OF MEDICAL PHONOGRAPHERS.

SIR.—Will you kindly grant me space to express a hope that any members of the profession who use shorthand, and may be intending to join our Society, will do so at once by a communication to Dr. Neil. Warnford Asylum, Oxford? We are anxious to include as many as possible before the general meeting on July 30th. Although we have now 154 members, we find that there are still many who should join and have not yet done so.

Among the visitors whose presence we hope for on July 30th, at 4 P.M., at 20, Hanover Square, are General Sir Charles Wilson, K.O.B., K.C.M.G., the Director-General of Military Education, and Dr. J. H. Gladstone, F.R.S., who has used phonography as an aid to scientific work since 1848.

I may add that the varied service the Society is rendering to its members far exceeds, both in degree and character, our early anticipations. To this many members could bear strong testimony.—I am, etc.,

Cavendish Square, W., July 15th.

W. R. GOWEN

President.

METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.

SIR.—Dr. O. Wunderlich's letter in the *BRITISH MEDICAL JOURNAL* of July 13th will have dispelled many wrong notions on the subject of the Metropolitan Provident Medical Association. I have for a long time thought out the matter of attending the poor who really cannot afford to pay ordinary fees any more than and in the same proportion to the ordinary householder with an income of £20 or so a year not being able to keep his carriage. The Metropolitan Provident Medical Association serves as an association conducted by members of the profession themselves, a club, provident association, or whatever it may be called, conducted on the very lines which the *JOURNAL* has on more than one or two occasions suggested. So let me, as one whose lot is cast in a

district where the labouring classes live, refer my colleagues to this Association. How much better would it be for the wretched keepers of sixpenny, fourpenny, and threepenny dispensaries who are qualified medical men to attend their poor under the auspices of this Association rather than to become the laughing stock of their professional brethren as well as placing themselves in a mean position towards the public? I would, too, with Dr. Wunderlich, advise those of our profession who serve under—and are sweated by, shall I say?—a lay committee to manage their dispensaries for themselves. The remedy is in the hands of the profession itself.—I am, etc.,

Tottenham, July 18th.

G. HENKLOTS VOS.

SIR,—I quite agree with Dr. Wunderlich that it is the supineness of the medical officers which allows the branches to be mismanaged. Having been one of the promoters of the Tottenham branch, and having continued till last year as a member, I found myself usually, till Dr. Wunderlich joined, the only medical member of the Committee present; there were nine at first and later ten other doctors on the staff, and one hour a month was given to the meetings of the Committee. With regard to the payment, I found it work out with the penny paid for each attendance at 101, or 101.1. The trouble I found was one common to all clubs, that of having a few unreasonable members, who would not, when wanting attendance, send before 10 o'clock, but expected immediate attention to a call at any time. Frequently after a long round I have come in to find five or six messages from different directions, all of which might have been sent early, and I think in any rules for an institution of the kind this point ought to be very strongly insisted on that a special fee must be paid for a special call if the case is urgent; it is worth it in the interest of the patient: and if not the message will be sent at a proper time, otherwise the doctor's time is remorselessly wasted, to save a halfpenny card or a walk to his house, and he has either to walk a few extra miles daily or take his horse and carriage over the same ground two or three times in the same day.—I am, etc.,

Bournemouth, July 18th.

GEO. B. BRALE, M.D.

MEDICAL AID ASSOCIATIONS.

SIR,—In view of the discussion on this topic at the coming congress of the British Medical Association, perhaps you can kindly republish the subjoined pledge, which has been signed by all the practitioners, with one exception (and he agrees with the principle) in and about Malvern. I believe the general adhesion to this pledge has prevented the formation of a medical aid association here, and recommend similar action in other districts.—I am, etc.,

Malvern, July 18th.

STANLEY HAYNES, M.D.

"We the undersigned members of the medical profession of Malvern and its neighbourhood, taking into consideration the fact that there are well established provident dispensaries in our midst, pledge ourselves not to undertake the care of families of members of friendly societies at a contract rate of payment."

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL STAFF EXCHANGE.

The charge for inserting notices respecting Exchanges in the Army Medical Department is 3s. 6d., which should be forwarded in stamps or post office order with the notice. The last post on Wednesday is the latest by which these announcements can be received.

AN Officer of field rank, who expects to be ordered abroad this trooping season, wants an exchange with an officer of the same rank who will have about three years to do at home.—Address Medicus, United Service Club, Stephen's Green, Dublin.

THE NAVY.

MR. WILLIAM DOUGHTY has been appointed Surgeon and Agent at Torcross and Hallsands, July 18th.

INDIAN MEDICAL SERVICE.

BRIGADE-SURGEON JOHN MARTIN COATES, M.D., late Bengal Establishment, died of cholera at Calcutta on July 10th. He was appointed

Assistant Surgeon, August 4th, 1856, and Brigade-Surgeon, January 25th, 1861. He retired from the service July 9th, 1880. He served in the Indian mutiny campaign in 1857-58, and had received the medal for that campaign.

Surgeon-Lieutenant-Colonel G. W. CALTHROP, M.D., Bengal Establishment, is promoted to be Brigade-Surgeon-Lieutenant-Colonel from March 25th, 1893. He dates as a Surgeon from April 1st, 1859, and as Surgeon-Lieutenant-Colonel from April 1st, 1880. He was in the Afghan war in 1879-80, and was in the engagement at Ali Masjid, and in the operations round Cabul in December, 1879, in saving the investment of Sherpur (medal with clasp).

Surgeon-Lieutenant-Colonel W. A. C. FOX, Bengal Establishment, is also promoted to be Brigade-Surgeon-Lieutenant-Colonel from March 25th. He entered as Assistant Surgeon, October 1st, 1859, and became Surgeon-Lieutenant-Colonel twenty years thereafter.

THE VOLUNTEERS.

SUBRON-MAJOR C. ARNOT, M.D., 1st Kent Artillery (Eastern Division Royal Artillery), is promoted to be Surgeon-Lieutenant-Colonel, July 17th.

Messrs. THOMAS W. J. ALLEN and GEORGE H. GOSWORTHY are appointed Surgeon-Lieutenants in the 1st Lincolnshire Artillery (Western Division Royal Artillery), July 17th.

Surgeon-Lieutenant J. C. WIGNOT, 2nd West Riding of Yorkshire Artillery (Western Division Royal Artillery), is now appointed Lieutenant in the same corps, July 17th.

Surgeon-Lieutenant W. D. FRASER, M.D., 2nd Volunteer Battalion the Royal Welsh Fusiliers, is promoted to be Surgeon-Captain, July 17th.

MR. MARK RINGWOOD RICH is appointed Surgeon-Lieutenant in the 2nd Tower Hamlets Rifles, July 17th.

CHANGES OF STATION.

THE following changes of Station amongst the officers of the Army Medical Staff have been officially notified to have taken place during the past month:

	From	To
Surgeon-Major-General T. Welch	Madras	Bengal.
Surgeon-Lieut.-Col. J. S. Forrester	R. H. Guards	1st Life Guards.
Surgeon-Major E. H. FENN, C.I.E.	Coldstream Gds.	Scots Guards.
" H. J. McMichael	Egypt	Dumfriesshire.
" P. Mulvaney	Ipswich	Bedford.
" R. H. Maclean	Madras	Chatham.
" W. J. Foster	Hull Regt.	"
" W. B. Thompson	York	Strathclyde.
" A. H. Morgan	West Africa	Woolwich.
Surgeon-Capt. P. L. Josling	West Africa	Coldstream.
" A. P. H. Griffiths	Wrexham	Blackpool.
" J. F. Bateson, M.B.	York	Albion.
" J. S. Davidson, M.B.	Arson	Exeter.

MEDICAL ARRANGEMENTS IN MOUNTAIN WARFARE IN INDIA. Some pregnant remarks on medical and sanitary arrangements in Indian mountain warfare fell from Major F. C. Carter, Royal Berkshire Regiment, during his recent lecture at the Royal United Service Institution on the 3rd inst., on Mountain Warfare. He pointed out the danger of false economy in cutting down the medical staff and the number of field hospitals required for hill campaigns exemplified with the Indian Field Force of 1892, when, owing to fever, sunstroke, and cholera, the resources of the medical department with the force were severely taxed. Major Carter pronounced the stretchers now in use as quite unsuitable for steep hill sides. The remarks on sanitation emphasized the necessity of a far more careful inspection of the *minutia sanitatis* as he terms them.

THE SOBRIETY OF THE ARMY.

THE money grant of £200 by the late Minister for War to the treasury of the one-year old Army Temperance Association, was an unmistakable proof of the belief at headquarters in the value of abstinence as conducive to the health and good conduct of British soldiers. Lord Roberts's evidence is that 14,000 abstaining soldiers are equal to 15,000 non-abstainers, a remarkable testimony to the superior mental and bodily vigour of the abstaining men, as well as to the greater economy of a sober army. Sir George White has stated that courts-martial in the third of the Indian forces which is abstinent are at the rate of only 3.25 per 1,000, against 12.5 per 1,000 in the non-abstaining two-thirds. In Britain there are 100 soldiers now on the rolls of the Army Temperance Association, and the Duke of Connaught recently found 1,235 teetotallers, or 9 per cent. of the division stationed at Aldershot. This new organized temperance movement in the forces at home has the active support and co-operation of the Duke of Connaught, Lord Wolseley and Roberts, the Chaplain-General, and many general officers, with a goodly number of the medical and surgical service.

MILITARY ADVICE ON MEDICAL SUBJECTS.

THE *Indian Medical Record* of June has a leading article on "The military medical staff of the British Army in India," and supports the contention of the late Surgeon-General, Lord Curzon, set forth in the *Indian Medical Record*, regarding the determination in the military command of the medical staff.

The article is too long for reproduction, but should be read by medical officers. The following passage is worth extracting: "Our military medical requirements have evidently been worked out and based on station hospital work, which has been provided a small percentage of a reserve for all other and war contingencies, and that our strength of medical officers and substantiates has been used at dangerously low figures because quite plain when the smallest demand is made for medical services."

The late Sir John Stansfeld, the Secretary of State for India quite recently, in reply to a question in the House, stated that his "military advisers" had recommended that the medical staff in India was quite sufficient for all requirements. Here we have the "military" adviser; but what, it may be asked, do the "medical" advisers say?

EMPLOYMENT OF RETIRED ARMY COMPOUNDERS.

A NOTE has been published by the Medical Staff Officers' Association, stating that the Local Government Board have been asked to consider the appointment of retired army compounders as dispensers to hospitals, etc.

VOLUNTEER PROMOTION.

A CORRESPONDENT, referring to the promotion of Volunteer medical officers to brigade rank, says: The *Army List* shows that in 1894 the senior medical officer had been promoted, while in 1893 had a junior been selected. This shows that selection has hitherto been the exception and not the rule.

"Theoretically, no doubt, all such promotion is by selection although the seniors are seldom passed over."

PRINCIPAL MEDICAL OFFICERS IN THE ARMY LIST.

REMARKS LATELY MADE draw attention to the fact that at last principal medical officers in the head quarter staff of districts have their names inserted in proper alphabetical sequence in relation to other district officers. This point, small in itself and yet of no little significance, has been pressed by us on the attention of the authorities, and we are glad that the names of medical officers are at last to be removed from the ragged end of staff lists.

MEDICO-LEGAL AND MEDICO-ETHICAL.

ASSISTANTS AND INCIDENTAL FEES.

PERHAPS although we have repeatedly answered similar questions to those submitted we quote once more the following rule in its entirety from the *Code of Medical Ethics*, 4th ed.: "The question of right to the fees for services given by assistants and *locum tenentes* in coroners' cases is a vexatious one, with the view to avert any disturbing or other mischievous effect on the relations between practitioners and their assistants, to discontinue the practice—sustained as it is by the *locum tenens* wage and its indispensable features—that such and all other fees belong to the principals for the time being unless otherwise agreed at the time of the mutual engagement; in reference to which, however, it may be expedient to note that the entire services of an assistant—be he a yearly or (as in the case of a *locum tenens*) a temporary one—belong to the employer, to whom he is rightly held responsible for all moneys received in his professional capacity."

GRATUITOUS ATTENDANCE ON THE FAMILIES OF DECEASED MEDICAL MEN.

RATHBON.—A careful perusal of the foregoing rule will enable our lady correspondents to see how far she is entitled to the gratuitous services of the family, nor can we doubt but that if the medical attendant on her daughter were made acquainted with the alleged fact of her having been "left totally unprotected for and had thus to pass her own living" he would willingly forego the charge in question. "All legitimate practitioners of medicine their wives and children, while under the paternal care are entitled that as a matter of right, but as professional courtesy to the reasonable and gratuitous services, nursing and like expenses extended, of the family resident in their homes, or near neighbors, and whose assistance may be desired. In the case also of near relatives who are poor or less dependent on a professional brother other than wealthy it will likewise be well, and it is recommended to furnish the usual fee. On the other hand, when a daughter or other relative is independent of the father, or the widow or other person of a profession, or left as affluent or well-to-do, no special charge should be regarded as necessary, unless some fee of honor or other special request render the attendance of the practitioner a professional responsibility, in such case the rule need not apply. Moreover, if a wealthy member of the faculty seeks professional aid, and courteously offers the assistance of a fee it should not be refused for his pecuniary condition should not be regarded as the ground on which the fee should be refused, and it would not wish to incur the charge." (*ibid.*, Chap. II, sec. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

LOANING AND INFLECTION.

ON July 20, at the Court of Appeal, composed of Lord Esher (the Master of the Rolls), Lord Justice Kay and Lord Justice Lindley, the appeal of the defendant in the case of *James v. James* was argued. The case had been recovered by the plaintiff on the ground that while his wife and daughter were staying in furnished apartments at the defendant's house

they caught scarlatina. The date last is an instance of a case at law, and in the case of *James v. James*, the plaintiff, a husband, furnished. The plaintiff, who resides at Ladbroke, sent his wife and two children to lodge with the defendant, and while there, as alleged, contracted scarlatina from the grandchild of the defendant, who happened to be on a visit to him. The question to be decided was merely one of law.

The Master of the Rolls, in giving judgment, said, notwithstanding the verdict of the jury, was bound to find the plaintiff's wife and children contracted the scarlatina from the grandchild of the defendant, and that he was not liable for the damages claimed. The appeal must therefore, be allowed with costs. Lord Justice Kay and Lindley concurred.

UNIVERSITIES AND COLLEGES.

UNIVERSITY OF DURHAM.

THE first woman graduate of the University of Durham was Miss Kate Bryant, who received the degree of Bachelor of Science at the meeting of Convocation on June 20th. The degree was granted under the powers granted by the supplementary charter received last year. Women students can receive instruction in the various subjects of the Medical and science Faculties at the College of Medicine, or the College of Science, Newcastle-on-Tyne.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following gentlemen were at the quarterly meeting of the Council on Thursday, July 11th, elected to the various offices for the ensuing year.

Honorary Professors.—Charles Stewart, M.R.C.S. Eng., Conservator of the College Museum (St. Thomas's Hospital), and of the College and stated, John Alfred Cooper, M.R.C.S. Eng., M.R.C.P. (St. George's Hospital), on Infantile Syphilis; Leonard Ernest Hill, M.D. Lond., M.R.C.S. Eng. (University College Hospital), on Cerebral Pressure and the Cerebral Circulation.

Arris and Gale Lecturer.—Ernest Henry Starling, M.D. and B.S. Lond., M.R.C.S. Eng. (Guy's Hospital), on the Physiology and Chemistry of the Blood. *Honorary Women Lecturer*.—Walter George Spencer, F.R.C.S. Eng., M.D. and B.S. Lond. (Westminster Hospital), on the General Pathology of the Blood.

Pathological Curator.—James Henry Targatt, M.B., B.S., and M.D. Lond., F.R.C.S. Eng. (Guy's Hospital), re-elected.

Anatomical Assistant in the Museum.—Richard Higgins Burn, B.A. Oxon., re-elected.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

SCHOOL PRIZES.—The Barker anatomical prizes have been awarded to N. H. Alcock and C. J. Patton (equal). A special prize has been awarded to W. J. Sweeney. The Carmichael Scholarship has been won by J. J. Palmer. In Surgery the gold medal has been won by L. M. O'Brien, the silver by G. A. Robinson. In Practical Histology the first prize was gained by D. Hadden; the second by H. Hall. In Practical Chemistry P. A. Foster gained the first prize, and C. C. Mack and W. J. Anglin were equal for the second prize. In Public Health and Forensic Medicine A. I. Bades gained the first prize and Miss C. L. Williams the second. In Materia Medica R. H. D. Pope won the first prize and G. B. McDonald the second. In Practical Pharmacy S. R. Godkin obtained the first and M. Gavin the second prize. In Biology M. Gavin gained the first prize and W. McLorinan and W. J. Anglin were equal for the second.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, IRELAND.

THE preliminary examination for the entrance to the medical colleges of the Royal Colleges of Physicians and Surgeons in Ireland, for the session 1895-96, will be held at the Royal College of Physicians, 1st and 2nd. Prospectuses can be had on application to the Registrar, at the Royal College of Surgeons, 51, Stephen's Green, W. 1.

SURGEON'S HALL, EDINBURGH.

MR. J. RYLAND WHITTAKER, F.R.C.S. Lond., F.R.C.P. Edin., F.R.C.S. Edin., has been elected Lecturer on Anatomy, at Surgeons' Hall, School of Medicine, Edinburgh, in place of Dr. McDonald Brown, who has resigned with the view of going to London.

OBITUARY.

DAVID J. BRAKENRIDGE, M.D., F.R.C.P.E.

Consulting Physician to the Royal Infirmary, Edinburgh.

By the death of Dr. Brakenridge the medical profession in Edinburgh has lost one of its most eminent and, perhaps, its most genial members. Since the death of Angus Macdonald this is the first break in the front rank of the active staff of the school.

David J. Brakenridge was born at Ban-eglower, Perthshire, fifty-six years ago, the son of a medical officer in the service of the East India Company; was educated at Perth Academy, and subsequently in the Arts course of the University of Edinburgh. He then proceeded to the study of medicine, graduated M.D. in 1869, L.R.C.S. in 1870, and F.R.C.P.E. in 1877.

His first appointment was as Physician to the Edinburgh New Town Dispensary. Later he was in succession Extra

Physician, Physician-in-Ordinary, and Consulting Physician to the Royal Hospital for Sick Children. In 1876 he was appointed one of the Physicians to the Royal Infirmary, a post he held for the usual period of fifteen years; and in July, 1891, Physician to the Chalmers Hospital. He was Medical Examiner for the Edinburgh district for the Scottish Union and National Assurance Company. At the time of his death he was one of the Managers (for the second time) of the Royal Edinburgh Asylum at Morningside. He had also been a Director of the Orphan Hospital.

His publications were numerous and important. The first, On the Influence of a Digestive Habit in the production of Tuberculosis, and Indications for Treatment drawn therefrom, appeared in 1863; A Contribution to the Theory of Diathesis, in 1869, a paper which had the distinction of being quoted by Darwin in *The Descent of Man*; in 1875 appeared The Prevention and Treatment of Scarlatina and other Infectious Diseases by the Internal Administration of Disinfectants; papers On the Action of Citrate of Caffeine and Oxide of Zinc followed. Then in 1890 came The Present Epidemic of so-called Influenza, and in 1892 his last paper, The Transfusion of Human Blood in the Treatment of Pernicious Anæmia. Such is the brief outline of his life's work now too early closed. Such the scaffolding, but what a superstructure and what a filling up!

Very soon after his admission to the Royal Infirmary, Dr. Brakenridge was recognised, at first by a select few, later by a large body of students, as a close observer, a thoughtful physician, and one of the most sympathetic and attractive of teachers. He seemed always to be seeking after the determination of new points and the discrimination of lines of difference. This habit of mind was seen more particularly in his papers on the influence of the digestive habit, on diathesis, and his most carefully thought out paper on influenza, published when there was less to be said with certainty on the matter than now.

During the whole fifteen years he was physician to the infirmary his clinical lectures were masterly studies most patiently elaborated on the subject on hand. Hence it came that his clinics were for many years frequented by the more thoughtful students, both of the University and the extra-academical school of medicine, and the post of resident physician to the wards under his charge a prize much sought after.

At the societies, specially the Medico-Chirurgical, his contributions were always pre-eminently thoughtful and his observations bore the stamp of truth. He had the honourable position of introducing to the Society on several occasions important topics for discussion; for example, on Transfusion, Pernicious Anæmia, and on Influenza.

In the Royal College of Physicians he was especially at home. For many years he was a member of the Council, where his shrewd judgment, his logical grasp of principle, and his unflinching manliness made for him a quite unique position of confidence. With all this he ever maintained a courtliness of manner and expression that made him beloved even by those from whom he differed most. He was known on more occasions than one to differ in the strongest way from other colleagues and to express his views in no half-hearted fashion and yet leave a meeting after some such encounter arm-in-arm with the man whom he had hit hardest. For a number of years he was librarian to the College, and till the development of his last sad illness he held the position of examiner. But for this illness it was well known that he would have been asked to assume the Presidential Chair in November next. The intervention of the mortal malady had been anticipated by him. While not then looking on the continuance of symptoms with serious alarm he concluded some two months ago that in the interests of the College it was better that he should not face the arduous responsibilities which necessarily attended the occupancy of that chair.

It was qualities like these which won for him the thorough confidence of a large number of practitioners, both among his own students and older men, so that latterly his consultation practice had become very considerable.

Never very robust, he had, during the past four years, suffered from occasional attacks of hæmaturia, and six weeks ago it became plain that there was malign vesical disease. He died, as he had lived, with uncomplaining Christian fortitude.

He was carried to his grave in the Dean Cemetery on July 13th amid universal regret. The funeral was very large and representative, the many members of his own profession being specially conspicuous.

Dr. Brakenridge was a deeply religious man, and followed with close and intelligent interest the movement of ecclesiastical affairs in Scotland. For twenty-five years he was an elder in the Free Church, and for the last twelve years under the ministry of his intimate friend, Dr. Walter C. Smith, the distinguished author of *Obrig Grange*. He took a keen interest in art, and was himself a painter of no mean order. His interest, as usual, took practical shape, for he was a lay member of the Council of the Society of Scottish Arts and of the Scottish Arts Club.

It is difficult to trace to their sources the elements of the personal charm of Dr. Brakenridge. Perhaps one comes nearest the mark when one quotes what was said of the late Dean Stanley: "He was so pleasant." That really sums it up: he was so pleasant. He was always brightness and gentleness personified, and his ways were so winning. From his finely-strung and sensitive nature there constantly came a quick sympathy that touched the heart. And it was always so, for there was an absolute uniformity and perfect sincerity about him that falls to the lot of the few. He was indeed one of Nature's nobility.

We regret to announce the death of Mr. O. S. HALL, surgeon, of Carlisle, which took place on July 6th. He was one of the oldest practitioners in the city, and the holder of several public appointments. He studied at the London Hospital, and during his course was one of the medical visitants in the London cholera plague of 1874, after that he served on the medical staff in the Crimea. He took the diplomas of M.R.C.S. Eng. in 1856 and L.S.A. in 1857. After his return home he spent eighteen months in Manchester, whence he moved to Carlisle. In 1862 he became Certifying Factory Surgeon, in 1864 Medical Officer to the Workhouse Hospital, in 1875 Medical Officer to the Carlisle Rural Sanitary Authority, and in 1888 Surgeon to the City Police. He always took great interest in Volunteer movements, and attained the rank of Brigade-Surgeon-Lieutenant Colonel of the North-West Brigade. Of scientific subjects he was especially fond, and was president of the Carlisle Microscopical Society for many years. His name is especially identified with workhouse nursing, in the reform of which he was one of the pioneers. He was universally respected, and his death will cause general regret through a wide circle of friends.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently passed away are Dr. Sébire, Member of the French Senate for La Manche, aged 88; Dr. Elias Rodriguez, Professor of Therapeutics and Forensic Medicine in the University of Caracas; and Dr. José Maria Teixeira, Professor of Pharmacology and Therapeutics in the Medical Faculty of Rio de Janeiro.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

ENGLISH URBAN MORTALITY IN THE SECOND QUARTER OF 1895. THE vital and mortal statistics of the thirty-three large English towns dealt with by the Registrar-General in his weekly returns are summarised in the accompanying table. During the three months ending June last 83,278 births were registered in these thirty-three towns, equal to an annual rate of 31.5 per 1,000 of their aggregate population, estimated at rather more than ten and a half millions of persons in the middle of this year. In the corresponding periods of the three preceding years the birth-rates in these towns was 32.9, 32.2, and 30.4 per 1,000 respectively. In London the birth-rate last quarter was 30.8 per 1,000, while it averaged 32.1 in the thirty-two provincial towns, among which it ranged from 26.3 in Huddersfield, 23.5 in Halifax, 28.6 in Brighton, and 25.8 in Croydon to 38.0 in Hull, 35.2 in Salford, 36.4 in Sunderland, and 37.5 in Liverpool.

During the quarter under notice 47,060 deaths were registered in the thirty-three towns, corresponding to an annual rate of 17.8 per 1,000, against 19.5, 19.8, and 17.4 in the second quarters of the three preceding years, 1892-3-4. In London the rate of mortality was equal to 16.7 per 1,000, while it averaged 18.0 in the thirty-two provincial towns, among

which it ranged from 12.4 in Croydon, 14.1 in Portsmouth, 15.1 in Leicester, 15.7 in Cardiff and in Nottingham, and 18.3 in Swansea to 21.2 in Preston, 22.4 in Burnley, 23.1 in Bolton, 23.9 in Manchester, and 24.4 in Liverpool. The 47,060 deaths registered in the thirty-three towns last quarter included 1,314 which were referred to the principal zymotic diseases, equal to an annual rate of 1.7 per 1,000, in London the zymotic death-rate was equal to 1.5 per 1,000, while it averaged 1.4 in the thirty-two provincial towns, and ranged from 0.6 in Halifax, 0.7 in Croydon and in Bradford, 0.8 in Bristol and in Swansea, and 0.9 in Portsmouth, in Huddersfield, and in Leeds to 2.4 in Preston, 2.6 in Liverpool and in Salford, 2.8 in West Ham and in Manchester, 3.0 in Plymouth, and 3.4 in Bolton. The 1,314 deaths referred to the principal zymotic diseases in the thirty-three large towns included 1,173 which resulted from measles, 1,000 from whooping-cough, 625 from diphtheria, 781 from diphtheria, and from scarlet fever, 184 from "fever" (principally enteric), and 15 from small-pox. The fatal cases of measles which had declined from 2,794 to 1,000 in the four preceding quarters, rose again to 1,173 during the three months ending June last, in London the measles death-rate was 0.52 per 1,000, while it averaged 0.39 in the thirty-two provincial towns, among which this disease showed the highest proportional fatality in West Ham, Plymouth, Cardiff, Bolton, Manchester, and Newcastle-upon-Tyne. The deaths referred to whooping-cough, which had been 665 and 1,145 in the two preceding quarters, declined to 1,062 during the three months under notice, in London the death-rate from this disease was equal to 0.41 per 1,000, and corresponded with the mean rate in the thirty-two provincial towns, among which whooping-cough was proportionately most fatal in Salford, Burnley, Blackburn, Preston, Gateshead, Manchester, and Liverpool. The 325 fatal cases of diphtheria considerably exceeded the low number recorded in the corresponding period of last year, in London the death-rate from this disease was equal to 0.29 per 1,000, while it averaged 0.39 in the thirty-two provincial towns, and was highest in Preston, Salford, Cardiff, and Blackburn. The deaths from diphtheria, which had been 1,085 and 780 in the two preceding quarters, further declined to 781 during the three months ending June last, in London the diphtheria death-rate was equal to 0.41 per 1,000, while it averaged 0.39 in the thirty-two provincial towns, among which this disease showed the highest proportional fatality in West Ham, Wolverhampton, Cardiff, Birmingham, Birkenhead, and Burnley. The fatal cases of scarlet fever, which had declined from 585 to 385 in the five preceding quarters, further fell to 334 during the three months under notice, in London the death-rate from this disease was equal to 0.15 per 1,000, while it averaged 0.11 in the thirty-two provincial towns, among which scarlet fever was proportionately most fatal in Nottingham, Salford, Burnley, and Huddersfield. The deaths referred to different forms of "fever" (including typhus, enteric, and simple and ill-defined forms of "fever"), which had been 681 and 436 in the two preceding quarters, further declined to 391 during the three months ending June last, in London the "fever" death-rate did not exceed 0.07 per 1,000, while it averaged 0.16 in the thirty-two provincial towns, and was highest in

Liverpool, Salford, Sunderland, Birkenhead, and Portsmouth. The fatal cases of small-pox in the thirty-three towns, which had declined from 125 to 20 in the five preceding quarters, further fell to 13 during the three months under notice, of which 4 were registered in Derby, 3 in London, 3 in Liverpool, 3 in Oldham, 1 in Birmingham, and 1 in Bolton.

Infant mortality in the thirty-three towns, measured by the proportion of deaths under one year of age to registered births, was equal to 1.6 per 1,000 last quarter, against 1.8, 1.6, and 1.3 in the corresponding periods of the three preceding years. In London the rate of infant mortality was 1.31 per 1,000, while it averaged 1.45 in the thirty-two provincial towns, among which it ranged from 1.0 in Croydon, 1.07 in Huddersfield, 1.08 in Nottingham, 1.19 in Portsmouth, and 1.26 in Cardiff to 1.35 in Plymouth, 1.71 in Manchester, 1.77 in Bolton, 1.79 in Burnley, and 2.22 in Preston.

The causes of 707, or 1.5 per cent., of the 47,060 deaths in the thirty-three towns during the second quarter of this year were not certified, either by a registered medical practitioner or by a coroner. The proportion of uncertified deaths in London did not exceed 0.5 per cent., while it averaged 2.0 per cent. in the thirty-two provincial towns. The causes of all the deaths during the quarter in Croydon and in Plymouth were duly certified; in the other towns the lowest proportions of uncertified deaths were registered in Brighton, Wolverhampton, Derby, Bolton, and Oldham, and the highest in Birmingham, Liverpool, Sheffield, Hull, and Leicester.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns, including London, 4,260 births and 4,033 deaths were registered during the week ending Saturday, July 13th. The annual rate of mortality in these towns, which had increased from 16.4 to 17.5 per 1,000 in the four preceding weeks, further rose last week to 19.9. The rates in the several towns ranged from 9.9 in Huddersfield, 10.2 in Swansea, and 10.5 in Brighton to 26.4 in Preston, 27.4 in Wolverhampton, and 30.2 in Liverpool. In the thirty-two provincial towns the mean death rate was 19.0 per 1,000, and was 2.0 below the rate recorded in London, which was 21.0 per 1,000. The zymotic death-rate in the thirty-three towns averaged 4.3 per 1,000; in London the rate was equal to 5.3 per 1,000, while it averaged 3.6 in the thirty-two provincial towns, and was highest in West Ham, Leicester, and Preston. Measles caused a death-rate of 1.5 in Manchester and 2.5 in West Ham; whooping-cough of 1.3 in Birkenhead and in Oldham, and 2.1 in Burnley; "fever" of 1.1 in Sunderland; and diphtheria of 4.3 in Wolverhampton, 4.5 in Bradford, 4.8 in Salford, 5.3 in Leeds, 6.5 in Preston, and 7.5 in Leicester. The mortality from scarlet fever showed no marked excess in any of the large towns. The 72 deaths from diphtheria in the thirty-three towns included 50 in London, 5 in West Ham, and 4 in Liverpool. One fatal case of small-pox was registered in London, but not one in any of the thirty-two large provincial towns. There were 79 small-pox patients under treatment in the Metropolitan Asylums Hospitals and in the Highgate Small-pox Hospital on Saturday last, July 13th, against 20, 24, and 25 on

Analysis of the Vital and Mortal Statistics of Thirty-three of the Largest English Towns during the Second Quarter of 1895.

the end of the three preceding weeks: 34 new cases were admitted during the week ending 24, 25, and 26 in the three preceding weeks. The number of deaths from plague in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had been 1,134, 1,281, and 1,281 at the end of the three preceding weeks, had further increased to 1,281 on Saturday last, July 27, and 1,281 new cases were admitted during the week, ending 24, 25, and 26 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

During the week ending Saturday last, July 28, 942 births and 282 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had been 19.3 and 19.4 per 1,000 in the two preceding weeks, further rose to 20.3 last week, and exceeded by 0.2 per 1,000 the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 12.2 in Dundee to 25.5 in Paisley. The corresponding death-rates in those towns averaged 17.3 per 1,000, the highest rates being recorded in Paisley and Greenock. The 282 deaths registered in Glasgow included 4 from diarrhoea, 10 from whooping-cough, 5 from measles, and 4 from "fever." Eleven deaths from diarrhoea were recorded in Paisley and 7 in Greenock.

COTTAGE HOSPITALS FOR INFECTIOUS CASES IN RURAL DISTRICTS.

A CORRESPONDENT has asked us to express our opinion on the subject of cottage hospitals for rural districts which are mainly composed of scattered villages of some thousand or two of inhabitants; whether such hospitals are to be commended, and whether, as a matter of fact, they are found to work well.

As to the latter question, we should say decidedly (treating the matter broadly) that infectious hospitals established in cottages are never likely to be commensurate substitutes for permanent structures specially built and adapted to the requirements of infectious disease isolation. It is true, as our correspondent points out, that the official memorandum of the Medical Department of the Local Government Board on Hospital Provision speaks of the feasibility of cottages fulfilling the needs of villages in some measure in regard of disease isolation; but we read the reference to these at best, subterfuges—as being in the nature of "any port in a storm," rather than an official declaration of the fitness of even isolated cottages to fulfil the demands of a district. Indeed, the whole aim of the department in question is well known to be to secure proper, adequate, and therefore—and pre-eminently—permanent special buildings for isolation purposes; but undoubtedly even a rudimentary hospital is better than having a number of improperly home-treated cases of infectious disease, acting as so many foci for disseminating sickness. Beside which, it may well be that a county council would look askance on proposals to expend the rates on such questionable methods of isolation, and that they might, by some central scheme, include several adjacent sanitary areas unprovided with any or possessing only inadequate means of disease repression; the Hospitals Act being in point in this direction. And certainly sanitary authorities will be well advised to abandon all temporary means in favour of separate or joint action on other and better lines.

Nevertheless, there are many bodies which have tried cottage hospitals, and in order to meet our correspondent's wish we name a few taken haphazard from a recent Parliamentary return on the subject of hospital accommodation in England and Wales: Bodmin, three-roomed house; Brecon, detached eight-roomed cottage and garden; Halstead, two cottages in an acre of ground; Burnley, row of four cottages, converted into a hospital, within three yards of a public road; Eastington rural district, detached six-roomed cottage; Newport (Salop) urban and rural districts, small cottage with kitchen, pantry, and one bedroom.

FEE FOR PAUPER MIDWIFERY.

"ENQUIRER" writes saying that he was called to attend a midwifery case in charge of a woman, as the infant at birth showed slight signs of life, and that when he arrived at the patient's house, some miles off, three or four hours after delivery, he found the child dead. He asks whether he is entitled to a fee of 10s., his services having been required for the child rather than for the mother.

"A." We consider our correspondent is entitled to the fee in question as medical attendance required for an infant immediately after birth, apparently for debility at birth, can hardly be considered a separate and distinct duty from attendance on the mother, who no doubt in this case also received medical attention.

LUNACY CASES IN WORKHOUSE HOSPITALS.

"JUNIOR" has now stated his case more clearly, although not with all the details. Presumably the patient referred to is a pauper (or is in such circumstances as to practically become one for the purposes of the operation of the Lunacy Act). If so, only one medical certificate is required, and "Junior's" difficulty does not arise. Indeed, this medical certificate is to be signed by the medical man called in to do so, by the justice acting in the case; and the justice may select any registered medical practitioner, as, for example, "A." or "B." or some other. But if, in the circumstances described, the case should by chance be a "private" one, then, of course, "A." and "B." could not both sign "medical certificates" in regard to it.

THE PLAGUE IN CHINA.

MACAU (Macao), a Portuguese settlement thirty miles from Hong Kong along the coast, is severely affected by plague. The disease first appeared in May, 1894, but only 8 cases occurred then, importations evidently, and the authorities

believed that their sanitation and strict quarantine had succeeded in preventing an inroad. The immunity of Macau during the whole of 1895, whilst the only two towns it is in daily communication with by steamer—namely, the cities of Canton and Victoria in Hong Kong were decimated—is peculiar.

In February, 1895, plague broke out in the fish market at Macau, and from that time until now (June 12th) the disease has raged in an epidemic form. The Hong Kong Government inquired officially as to the real facts as soon as the rumour reached them, but the Macau Government again and again denied the presence of the epidemic until the month of June. Private inquiries elicited the truth that plague was causing havoc, and in the month of April Chinese passengers from Macau were prohibited from landing in Hong Kong.

There are no official returns to guide one as to the probable mortality. During the second week in May, however, it is known that as many as 70 to 80 burials took place daily owing to this disease. At the present date, June 12th, the death-rate is 15 daily. When visited by our correspondent during the first week in June Macau presented all the appearance of a plague-stricken city. Junks and sampans in the harbour were drawn up at a considerable distance from the shore, as if to avoid contamination. The quays, usually swarming with people, were well-nigh deserted. The streets were empty, the population had left their houses and locked and barred their doors on the outside, a sure sign the houses were empty, and the few shops open were provision shops, with the shutters only half removed.

Of the population of some 80,000, only 10,000 were believed to be left in the town. The chief sufferers are, of course, the Chinese, but the Portuguese in Macau have also suffered severely. In Hong Kong, when plague raged in 1894, very few, some six or eight, of the English were attacked, showing as then stated an immunity to Europeans. The prevalence of the disease amongst Portuguese scarcely upsets that belief, as the residents in Macau are not European Portuguese. They are descended from the parent stock, which came to Macau 350 years ago, and freely intermarried with the Chinese.

An accession of Indian blood was imported from Goa, and a Eurasian tribe resulted of Portuguese-Indian blood, which is known locally as Macanese. These indigenous residents have acquired many of the ways, customs, and manner of living of the natives, and they are being attacked by plague in considerable numbers. With this explanation it will be seen that Europeans still preserve an immunity from bubonic plague. The disease is exactly of the same type as that met with last year in Hong Kong; the mortality is as severe, and the bacillus is identical. The sanitary and hospital arrangements in Macau are excellent, but with all these the pest has already lasted four months, and in all probability will maintain its hold for one month more. This is in exact accordance with the length of its stay in Canton and Hong Kong, and it may be taken as the typical period for which a town of any considerable size may be expected to suffer.

Plague is a disease which travels slowly, and it remains long in any community attacked, in spite of the fearful virulence of its ravages whilst prevalent. It will be asked, How did the disease reach Macau? The answer must be either from Canton or Hong Kong, but the disease in Hong Kong was a consequence of its presence in Canton. Hong Kong is practically a suburb of Canton, for, although eighty miles apart, 10,000 people travel between the places weekly. Macau was infected from the land side, that is, from Canton. With Canton as an infecting centre, we know now that the disease spread in a spreading circle, and that Macau, some 100 miles from Canton, was attacked seven months after the disappearance of the disease in Canton. Assuming that it had started from Canton during the height of the epidemic there, say in May, 1894, it took nine to ten months to travel 100 miles. That it is a soil-bred and a soil-supported disease there seems little doubt, and the belief that animals, especially rats, are the carriers, daily receives confirmation.

Reports, which are fairly authentic, have it that both Amor and Foo Chow are, or have been lately, infected by plague.

Hong Kong is entirely free from plague this summer.

INDIA AND THE COLONIES.

NEW SOUTH WALES.

In his anniversary address in the Royal Society of New South Wales, the President, Dr. Anderson Stuart, Professor of Physiology in the University of Sydney, deals with various matters of interest and importance to the Colony of New South Wales at the present time or in the near future. He first discusses the supply of artesian water in Australia. He then gives an account of an expedition which is to be undertaken to bore an adit in order to throw light on the formation of coral islands; the effect of certain animal poisons, and the prevalence of auricular and hydatid disease next come under discussion, and the address concludes with a reference to the organisms of sewer air, and a summary of the Sanitary Acts in force in New South Wales. The address is a most interesting one, the several topics are dealt with in a clear and concise way, and the attention of the reader is never allowed to become wearied. The account given of the poisonous secretions of the platypus and of the bush tick opens up subjects of some novelty, while the remarks upon sewer air show that a question which is exciting much attention in this country at the present time is also being investigated on the other side of the world. The review of the Sanitary Acts in force in New South Wales is interesting, and the hints as to the direction in which legislation should proceed in the near future are suggestive.

MEDICAL NEWS.

Mr. J. BUCKENHAM, M.R.C.S.E., etc., public vaccinator for the borough of Cambridge, has been awarded for the fifth time the Government grant for efficient vaccination.

At the Great Northern Central Hospital the Ladies' Association inaugurated on July 15th a bed which they had endowed by a contribution of £1,050 in honour of Dr. William Cholmeley, one of the founders of the hospital.

The fortieth yearly dinner of the Poplar Hospital for Accidents was held at the Holborn Restaurant on July 17th, under the presidency of Mr. John Aird, M.P. Donations to the amount of £3 5s were announced.

PRESENTATION.—On the occasion of resigning the office of secretary of the Forest Gate Shakespeare Society, Dr. Batteon was presented by the members with a timepiece and silver inkstand, in acknowledgment of the care and labour that he has devoted to the interests of the Society.

We are requested to state that Messrs. Oppenheimer, Son, and Co., Limited, of 14, Worship Street, London, E.C., have been appointed wholesale agents for the supply of the antitoxic serums prepared at the Pasteur Institute in Paris. The firm is now in a position to supply the diphtheria and the tetanus antitoxic serums.

THE BRUSSELS MEDICAL GRADUATES' ASSOCIATION.—The annual general meeting of this Association will be held on Monday, July 20th, at the Café Royal, Regent's Street, W., at 6.30 p.m. At 7 p.m. the members and their friends will dine together, and Sir Walter Foster, Dr. Glover, and Mr. Ernest Hart will be the guests of the Association. Any Brussels graduate wishing to be present at the dinner is requested to communicate with the Hon. Secretary, Dr. M. Greenwood, 23, Hackney Road, N.E.

THE BARBER SURGEONS' HOLDING.—Alderman Sir Stuart Knill, who, with the Governor of the Bank of England and Sir Joseph B. Emsdale, is heading a movement to secure from the Barber-Surgeons' Company their famous historical painting by Holbein for the Guildhall Art Gallery, has received a letter from Sir Francis Cook, of St. Paul's Churchyard, who offers to contribute £500 towards its purchase if during the next six months such a sum as the Barber-Surgeons' Company might consider sufficient could be raised.

VEAL POISONING AT LARNE.—A case recently occurred at Larne in which an old woman died with symptoms of inflammation of the stomach and bowels after partaking of veal which was unfit for food. The case is interesting because the analyst to whom the viscera were sent for examination, Mr. J. F. H. Jones, F.I.S.C., of Belfast, was able to demonstrate the presence of ptomaines. The jury acquitted the butcher of any culpable negligence in the matter.

PHARMACEUTICAL CHEMISTS IN GERMANY.—By order of the Prussian Government a statistical inquiry is to be instituted in Prussia concerning the number of chemists' shops, the number of assistants employed in them, and the amount paid for the goodwill at the last time of changing hands.

This statistical material when collected will form a basis for new legislation on the subject.

The annual summer meeting of the British Laryngological, Rhinological, and Otolological Association will be held at the house of the Royal Medical and Chirurgical Society, Hanover Square, London, W., on Thursday and Friday, July 25th and 26th, under the presidency of Dr. W. M. A. Wilson. The meetings will begin at 10 a.m. on each day. A discussion on the antitoxin treatment of diphtheria will be introduced by Dr. Sims Woodhead and Professor Sherrington. Several distinguished foreign guests have accepted invitations to take part in the proceedings, and members of the profession in this country will be welcomed.

The inaugural meeting of the Association of Asylum Workers was held at the rooms of the Medical Society of London on July 18th. The chief objects of the Association were stated to be to improve generally the status of asylum nurses and attendants, to secure the sympathy and cooperation of persons interested in institutional work, and to provide a home of rest and nursing for those engaged in asylum work. The honorary secretary is Dr. F. H. Walmesley, Metropolitan District Asylum, Dartford, Kent. The annual subscription for ordinary members will be 2s. 6d.; the life subscription for medical or honorary members, one guinea.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly Court of Directors of this Society was held on July 10th, at 8.30 p.m. Sir James Paget, President, took the chair. One fresh application for a grant was read from a widow, and assistance given. The death of a widow had occurred who had received grants since June, 1877, and had had £1,247 in all, her husband having paid 38 guineas to the funds of the Society. One new member was elected, and the deaths of two reported. A sum of £1,364 was voted to be distributed among the 53 widows, 9 orphans, 24 orphans on the Copeland Fund. A grant of £52 10s. was made for a widow under By-law 70. A legacy of £300 stock, duty free, was announced from the executors of Dr. Bisset Hawkins, V.P. The expenses of the quarter came to £62 11s.

MEDICAL VACANCIES.

The following vacancies are announced:

BOROUGH OF LEICESTER.—Medical Officer of Health and Public Analyst. Must devote his whole time to the duties. Total salary, £500 per annum. Applications, endorsed "Medical Officer of Health," to James Bell, Town Clerk, Town Hall, Leicester, by July 25th.

BOROUGH OF WEST HAM.—Medical Superintendent for the Borough Hospital for Infectious Diseases at Plaistow. Salary, £500 per annum, with annual increment of £10 up to £650, with apartments, furniture, and washing. Not less than 25 years of age. Applications, on forms provided, to be sent to F. E. Hillery, Town Clerk, Town Hall, West Ham, E., by July 25th.

BRADFORD INFIRMARY AND DISPENSARY.—Honorary Physician. Applications to the Secretary by July 25th.

BRITISH INSTITUTE OF PREVENTIVE MEDICINE.—Assistant bacteriologist in the Antisepsis Department. Salary, £150 a year. Applications to the Director by July 25th.

CHESTER GENERAL INFIRMARY.—Visiting Surgeon, doubly qualified. Appointment for two years. Salary to be determined by the Committee, with residence and maintenance in the house. Applications to the Chairman of the Board of Management, to be sent to the Hon. Sec., Chester Row North, Chester, by July 25th.

CHESTER INFIRMARY.—Resident Surgeon. Salary, £500 per annum with board, lodging, and washing. Applications to the Secretary by August 12th.

GREAT NORTHERN CENTRAL HOSPITAL.—Resident Surgeon. Salary, £500 per annum with board, lodging, and laundry provided. Applications, on forms provided, to be sent to Lewis H. Greston Kerr, Secretary, by July 25th.

HOSPITAL FOR WOMEN.—Soho Square.—Resident Surgeon and Physician. Appointment for three months. Applications to the Secretary by July 25th.

LEICESTER INFIRMARY.—Assistant Honorary Surgeon. Appointment for six months subject to re-election. Compensation of £200 per annum with board, lodging, and washing, together with board and residence in the infirmary, and washing. Applications to the Secretary, J. B. F. F. Jones, Esq., by July 25th.

LONDON HOSPITAL MEDICAL COLLEGE.—Master of the Hospital. Appointment for six months. Salary, £500 per annum with a pension of £100 per annum for services rendered, and a pension of £100 per annum for services rendered. Applications to the Secretary, J. B. F. F. Jones, Esq., by July 25th.

NORTH INFIRMARY.—Resident Surgeon, doubly qualified. Appointment for two years. Salary, £500 per annum. Applications to the Secretary, J. B. F. F. Jones, Esq., by July 25th.

NATIONAL SANATORIUM FOR CONSUMPTION AND OTHER AFFECTIONS OF THE LUNGS.—Resident Surgeon. Salary, £500 per annum with board, lodging, and washing. Applications to the Secretary by July 25th.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Assistant House Surgeon. No salary. Board and residence provided. Applications to the Secretary by July 27th.

PARISH OF CAMBERWELL.—Assistant Medical Officer and Assistant Medical Officer for the Infirmary at Havill Street, doubly qualified. Salary for the former at the rate of £250 per annum, increasing £50 annually to £300, with apartments, board, and washing, and for the latter, whose appointment will be for one year only, £50 per annum, with the same allowances. Applications to be forwarded at once to the Guardians Office, 29, Fencham Road, S.E.

ROYAL ORTHOPEDIC HOSPITAL, 20, Oxford Street.—Resident House Surgeon; must be M.R.C.S. Eng. and L.R.C.P., and unmarried. Salary, £200 per annum, with partial board. Applications to the Secretary by July 25th.

ROYAL VICTORIA HOSPITAL, Bournemouth.—House Surgeon and Secretary. Salary, £100 per annum, with board. Appointment for two years. Applications to the Chairman of the Committee by July 17th.

SAIFORD UNION INFIRMARY, Hope, near Eccles.—Assistant Medical Officer; doubly qualified. Salary, £200 per annum, with furnished apartments in the Infirmary. Applications, endorsed "Assistant Medical Officer," to T. H. Bapshaw, Clerk to the Guardians, Union Office, Eccles New Road, Salford, by July 25th.

SHEFFIELD GENERAL INFIRMARY.—House-Surgeon and Senior Assistant House-Surgeon, doubly qualified. Salary for the former, £250 per annum, with a prospective advance of £50 per year for the second and third years, and for the latter £50 per annum, with board, lodging, and washing. Applications to the "Medical Staff of the Sheffield General Infirmary, to the care of the Secretary," by July 18th. The election will take place on July 25th.

UNIVERSITY OF GLASGOW.—Lecturer on Surgery and Clinical Surgery at Queen Margaret College. Appointment for one year. Salary, £200 per annum. Applications to Alan E. Clapperton, Secretary of the Glasgow University Court, 51, West Regent Street, Glasgow, by July 30th.

UNIVERSITY OF GLASGOW.—Two Examiners for Degrees in Medicine to Examine in Chemistry and Materia Medica respectively. Applications to Alan E. Clapperton, Secretary of the Glasgow University Court, 51, West Regent Street, Glasgow, by July 25th.

YORK DISPENSARY.—Resident Obstetric House-Surgeon; unmarried. Salary, £200 per annum, with furnished apartments, coals, and gas. Applications to Mr. W. Draper, De Grey House, York, by July 25th.

MEDICAL APPOINTMENTS.

ALLAN, Ebenezer, L.R.C.P. and S. Edin., late House-Surgeon Glasgow Royal Infirmary, appointed Assistant Medical Officer Barony Parish Hospital, Barhill, Glasgow, *vice* James Rutherford, L.R.C.P. and S. Edin., resigned.

ALLAN, Fras. J., M.D. Edin., appointed Examiner in Medical Jurisprudence and Public Health at the University of Aberdeen.

BALLANTYNE, John W., M.D. Edin., appointed Examiner in Midwifery at the University of Aberdeen.

BELL, Dr., appointed Deputy Medical Officer of Health to the Lowestoft Town Council.

BERRY, Dr., appointed Medical Officer for the Enniskillen Dispensary District, *vice* B. Gamble, L.R.C.P., L.R.C.S.I., resigned.

BRADFORD, J. Rose, M.D., D.Sc. Lond., F.R.S., appointed Examiner in Medicine at the University of Aberdeen.

BUNCOMBE, Wm. Dewey, L.R.C.P. Lond., M.R.C.S. Eng., appointed Medical Superintendent of City of London Infirmary, Bow, *vice* C. H. Buncombe, F.R.C.S., resigned.

BOND, W. E., M.R.C.S., L.R.C.P., appointed Resident Medical Officer to the Brighton and Hove Hospital for Women.

BRUNZ, E. L. and L.M.R.Q.C.P.I., L.R.C.S.I., appointed Medical Officer and Medical Officer of Health Bannow Dispensary District, co. Wexford, *vice* Dr. H. Byrne, resigned.

GEORGE, Chas. F., M.R.C.S. Eng., L.S.A., reappointed Medical Officer for the Blyborough District of the Gainsborough Union.

GIBSON, R. J. Harvey, M.A. Aberd., appointed Examiner in Botany at the University of Aberdeen.

GIDLEY, Gustavus Geo., M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., appointed Medical Officer and Public Vaccinator for the Culmpton and Buterleigh and Kentishave and Blackboro' Districts of the Tiverton Union, *vice* Dr. T. H. Lloyd, resigned.

GRIFFITH, Thos. W., M.D. Aberd., appointed Examiner in Anatomy at the University of Aberdeen.

HUNTER, John, F.I.C., F.C.S. Edin., appointed Examiner in Chemistry at the University of Aberdeen.

JONES, Richard, M.D. Edin., D.P.H. Camb., reappointed Consulting Medical Officer of Health for the Merioneth County Council.

KEITH, Arthur, M.D., F.R.C.S., appointed to the Demonstratorship of Anatomy in London Hospital Medical College.

KIRK, Edwin W. D., M.B., M.R.C.S., L.S.A., appointed Surgeon under the Factories Acts to the Oulerton District, Sheffield, *vice* Henry Payne, M.R.C.S., resigned.

MACLACHLAN, John T., M.B., C.M. Glasg., appointed Assistant Medical Officer to Lanark District Asylum, Hartwood.

MINTER, L. J., M.D. Brux., M.R.C.S., L.R.C.P., L.S.A., appointed Medical Officer of the Workhouse of the Uxbridge Union, and Certifying Factory Surgeon for the Uxbridge District.

MOTT, F. W., M.D. Lond., F.R.C.P., M.R.C.S., appointed Pathologist to the London County Asylum.

PHILLIPS, Dr., appointed Medical Officer of Health to the Market Harborough Rural District Council.

RANDALL, Dr. W., appointed Medical Officer of Health to the Maesteg Rural District Council.

ROBERTHAM, A. J., M.R.C.S. Eng., reappointed Medical Officer for the Newton-on-Trent District of the Walsborough Union.

SMITH, Jas. Lorrain, M.A., M.D. Edin., appointed Examiner in Pathology at the University of Aberdeen.

STUART, J. A. Erskine, L.R.C.P. Edin., L.R.C.S. Edin., appointed Medical Officer of Health for the Borough of Halley, *vice* Alfred Swann, M.D., M.R.C.S. Eng., deceased.

THOMPSON, W. H., F.R.C.S., appointed Examiner in Physiology at the University of Aberdeen.

THOMSON, J. A., M.A. Edin., appointed Examiner in Zoology at the University of Aberdeen.

WARNER, Francis, M.D. Lond., appointed Examiner in Materia Medica at the University of Aberdeen.

WHITTAKER, J. Ryland, B.A., M.B. Lond., F.R.C.P. Edin., L.R.C.S. Edin., appointed Lecturer on Anatomy at Surgeons' Hall School of Medicine, Edinburgh, *vice* Macdonald Brown, F.R.C.S., resigned.

WILL, John C. Ogilvie, M.D. Aberd., appointed Examiner in Surgery at the University of Aberdeen.

WILKS, Dr., appointed Medical Officer of Health to the Blythe and Cuckney District Council.

WILMOT, Thos., L.R.C.P. Lond., M.R.C.S., appointed Honorary Medical Officer to the Bradford Infirmary.

MILSON, George, L.R.C.P. Lond., M.R.C.S. Eng., reappointed Medical Officer of Health for Newington.

MACKAY, John Sutherland, M.A., M.D., D.P.H., appointed Medical Officer of Health for the Burgh of Kircaldy, *vice* Henry Gordon, M.D., deceased.

DIARY FOR NEXT WEEK.

TUESDAY.

THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 2 P.M., Lecture at 4.

WEDNESDAY.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C., 2 P.M.—Lecture by Dr. Beover.

THURSDAY.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION, 20, Hanover Square, 10.30 A.M.—President's Address. 11 A.M.—Discussion on the surgical Treatment of the Accumbent Cavities of the Nose, introduced by Dr. Luc (Paris), Dr. Bryson Delavan (New York), Dr. John N. Mackenzie (Baltimore), Dr. F. H. Maworth (New York). 3 P.M.—Discussion on the Treatment of Chronic Laryngeal Stenosis, introduced by Dr. Sajous (Paris).

FRIDAY.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION, 20, Hanover Square, 10 A.M.—Exhibition of Cases. 11 A.M.—Discussion on the Therapeutics of Diphtheria, with special reference to Antitoxin, introduced by Dr. G. Sims Woodhead, Professor C. S. Sherrington. 3 P.M.—Discussion on the Surgical Treatment of Laryngeal Tuberculosis, introduced by Dr. Heinyng (Warsaw), Professor Krause (Berlin), Dr. Gleitsman (New York).

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

ANDERSON.—At Faversham, Kent, on July 14th, Maud, wife of Dr. C. M. Anderson, of a son.

OWEN.—On July 10th, at Hampton-on-Thames, the wife of Arthur Deaker Owen, M.R.C.S., L.R.C.P. Lond., of a son.

MARRIAGES.

CLAY—HEAVEN.—On July 16th, at St. Mary's, Moseley, by the Rev. Canon Wilkinson, D.D., assisted by the Rev. W. H. Colmore, M.A., Augustus Clay, M.R.C.S. and L.S.A. Lond., youngest son of the late Professor John Clay, Birmingham, to Katie, daughter of Henry Heaven, Esq., Chantry Road, Moseley. At home, "Ravenscroft," Alcester Road, August 14th, 16th, 21st, and 23rd.

NORTHCOOTE—ANDERSON.—On July 11th at Christ Church, Lancaster Gate, by the Rev. F. R. Hodgson, M.A., Rector of Little Gaddesden, assisted by the Rev. F. A. O'Brien, M.A., Vicar of Walton, Warwick, Ernest Augustus Northcoote, LL.B. Camb., Puisne Judge of the Supreme Court of Judicature, Jamaica, son of the late Stafford Henry Northcoote, of Belgrave Road, S.W., to Helena Jane (Lons), eldest daughter of Izett W. Anderson, M.D. Edin., formerly of Kingston, Jamaica.

DEATH.

GRIFFIN.—On July 16th, at the residence of his mother, 11, East Park Terrace, Southampton, John Griffin, M.B., of Port Elizabeth, South Africa, eldest son of the late R. W. Windy Griffin, M.D.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

Communications respecting Editorial matters should be addressed to the Editor, 49, Strand, W.C., London; those concerning business matters, non delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 49, Strand, W.C., London.

Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 49, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

MEMBER B.M.A. desires to hear of a home where a girl aged 16, an incurable cripple, would be received either free or for a small weekly charge.

Dr. A. H. BOYS (St. Albans) is anxious to hear of a home to which a child, crippled and disfigured by burns, could be sent to learn a trade.

Dr. K. K. would like to know where he could get information relating to hypodermic medication in syphilis, and also what results have followed the use (hypodermically) of olive oil, lanoline, and mercury in this disease.

Dr. B. asks for hints or cautions to be observed in the operation of circumcision in a child. Would be especially obliged for an opinion on the Mäny operation practised by Hajj Rāyah Bob who, he believes, dispenses with any ligatures or stitching of mucous membrane.

Dr. R. CROOK (Clayton-le-Moors) asks for suggestions in the treatment of a case of excessive secretion of saliva. There is no abnormality in the mouth or salivary glands; the patient is a man of 50, temperate, and a non-smoker. Belladonna and astringents have been tried with no good effect.

AN ALTERNATIVE FOR CONTRÉXVILLE.

A MEDICAL man of more than thirty years' practice has been for some time past suffering from the after-effects of influenza with suppressed perspiration. A physician has recommended his going to Contréxville for the baths and water. As he has a dislike to such banishment and absence from business, can any medical brother suggest any place in England excepting Bath, where he might look for the same results?

TREATMENT OF CHRONIC CONSTIPATION.

INMAN writes: Can any reader give me advice as to treatment in a case of chronic constipation of several years' standing? The patient is a lady, aged 42, and dieting, purgatives, massage, electricity, and enemas, have only given temporary or no result. There is no organic disease, but the circulation is somewhat feeble.

ANSWERS.

VERITAS.—Hypnotism in the hands of properly qualified medical men is legitimate, and many medical men avail themselves of it in suitable cases. The use of ozone has been found useful by members of the profession.

MEMBER B.M.A.—We would recommend our correspondent to obtain Davidson's *Hypnotism and Treatment of Nervous Diseases*, Young J. Pentland. It is not a small book, but, so far as we are aware, there is no short work on this great subject published in English.

GAMMA.—Under the Medical Act (1886) a registered medical practitioner can only require a foreign degree in medicine to be added to his name as an additional title in the Medical Register if he can satisfy the General Medical Council that he obtained such degree prior to the passing of the Act (Sec. 66).

NEIL-KROGGER.—The Medical Defence Union has had this matter in hand for some time, and is taking steps with the Metropolitan police to bring the offender to justice; but there are many difficulties yet to contend with before this can be done. The attention of the Postmaster-General has been called to the circulation of this pernicious literature, which there is power to stop under the Postal Acts.

Dr. GEO. B. BEALE (Bournemouth) advises "M.R." to send his patient to Bournemouth. There is no doubt some quality in the air, attributed

by some to its dryness and by others to the exhalations from the pines, which is very salutary to all suffering from lung affections, and more especially bronchial troubles, even during the last winter it was seldom that some hours enjoyable exercise in the open air was not possible even for invalids.

NOTES, LETTERS, ETC.

A MOWGLI IN REAL LIFE.

FROM Calcutta we have a new version of Mr. Kipling's Mowgli stories. A little girl was said to have been found a few years ago in the woods suckled by a she bear together with her own cubs. The child was sold to a menagerie, from which she escaped; after this she spent five years in a hospital and was discharged as incurable; the complaint being addition to the wild habits of her foster mother. Later we are told that this wild little waif was found wandering about the streets of Jaldapara, and was rescued by the manager of the Calcutta Zoo, where, under whose care she remained two years. Attempts were made to humanise the strange little creature, and to teach her human speech and to eat human food, but civilisation was too much for her and she died. We hope that Mr. Kipling will not narrow the feelings of the rising generation by giving a similar end to Mowgli. But did not Mowgli marry and enter the Forest Department?

A GRAVE RECEPTION OF THE CHOLERA.

A GRUESOME story reaches us from France of the preparations made by a certain mayor of a village to receive cholera, which showed more advice of resource than knowledge of sanitation. There was an outbreak of cholera, and the mayor received instructions from headquarters to make all necessary preparations and to take the required precautions as the epidemic was rapidly spreading. The worthy mayor was puzzled, for he did not know what to do and how to prepare for cholera. After a while he reported, however, that all was in readiness. On inquiry it was found that he had ordered a number of graves to be dug in the cemetery sufficient to bury the entire parish if necessary. He had certainly taken a very grave view of the situation.

THE ASSOCIATION AND THE INTERESTS OF GENERAL PRACTITIONERS.

Dr. T. GARRETT HORDER (Cardiff) writes: In a letter I received from the late Dr. Withers Moore, he made use of the following words in writing on the question of medical reform, and referring to the General Practitioners' Committee, which at that time he was endeavouring to get appointed: "But all this will be of no avail unless the general practitioners in a body shake off their apathy, and really know and express what they want." And you, Sir, writing last year on the subject of Dr. Arthur Welsford's paper, urged the members of the Association through the agency of their Branches to make known their opinions on this question. I have noted with pleasure that a considerable number of Branches have passed resolutions urging the Association to take the necessary steps to defend the interests of its members.

My object in writing you to-day is to call the attention of members to the resolution which will be proposed at the annual meeting by Dr. Arthur Welsford, and to urge them to be present and make their opinions known. The London meeting affords the best possible opportunity of gauging the feeling of the Association on this vital question. The Council will naturally be influenced by the amount of support the resolution obtains, and, if it voices the honest convictions of a vast majority of the members, the Council will take up the subject *en masse*, and do everything in their power to draw up a practical scheme for presentation to the members at an early date.

THE WATER SUPPLY AND DRAINAGE OF PARIS.

A RECENT Paris thesis—which has been added to the library of the British Medical Association—by E. ERON gives a sketch of the recent development of municipal hygiene in Paris and its influence upon health. By recent legislation a complete scheme of sanitation has been indicated dealing with water supply, drainage, and purification of sewage. The Parisians already receive a supply of spring water, caught at its point of emergence, carefully conducted through covered aqueducts, and protected from the air and from causes of contamination up to the tap, amounting to more than 100 litres a head a day. According to new regulations, all soiled water must be immediately conducted into the public sewers and carried beyond the city boundaries, and it is expected that in a dozen or fifteen years all this will be purified and utilised by application to the land. Already there is provision for dealing with one-fifth, and in the current year for one-third of the total volume received by the drains. According to M. ERON,

In 1874-75 the mortality was 42.69 per 1,000

In 1878-79 " " 30.43 " "

In 1884-85 " " 26.14 " "

In 1889-90 " " 25.60 " "

The great difference between the second and the third period marks the introduction of these two sanitary measures. The scheme is at present so far from complete, that it may be questioned whether other influences may not be at work to produce the improvement in the death-rate.

THE REALITY OF APPARENT DEATH.

Dr. GEO. STEELE FERRIS (Wimborne Street, W.) writes: In answer to Dr. Jennings's query: "Is the feeling of the pulse a sufficient delicate test to denote conclusively cessation of the heart's action?" I would answer emphatically "No."

In 1882, at Exmouth, Devon, I was called by a midwife to a case of accidental hæmorrhage at full term. The patient became collapsed and quite unconscious. The pulse at the wrist had grown weaker and weaker until it could not be felt, and the ear placed over the apex of the heart was the only means of telling that life was not extinct as natural breathing had ceased. From the time of her becoming unconscious I frequently injected ether subcutaneously, and directly breathing ceased performed artificial respiration: no means for transfusion was obtainable. Whilst performing artificial respiration, I frequently placed my ear over the heart apex to know if life was ex-

ting, and on one occasion for the space of at least one or two minutes there was no movement of the heart audible, and looking up to her mother I said: "Your daughter is dead." Raising myself I happened to put my fingers over the apex, and presently felt a slight flutter like a butterfly's wing. Setting to work again at artificial respiration and subcutaneous injections of ether, I presently found the heart getting a little stronger, and in course of time an effort at respiration was made. The pulse at the wrist could certainly not be felt for considerably over half-an-hour. The patient made an excellent recovery.

PUBLIC TRAPEZES.

DR. G. HERKLOTS Vos (Tottenham, N.) writes: I noticed lately at a seaside resort, the use by the public at large of the new trapezes on which the performer for his own pleasure and the inward delight of being seen and admired by others, holding on to a bar fixed to a moving pulley block slides down an inclined wire several yards, and on reaching the end brings the journey to a sudden end by elevating the knees or legs against a sack of some soft material. The shock of stopping is great. I saw both sexes, and even women of 50 years or so performing. I leave it to my professional brethren to judge of the result to uterus, ovaries, intestine, etc.

ICE CRADLING IN THE TREATMENT OF ACUTE DISEASE.

SURGEON-LIEUTENANT-COLONEL R. H. QUILL, A.M.S., writes: In the BRITISH MEDICAL JOURNAL for May 11th, 1895, Dr. Halkie Smith has an article On the Treatment of Acute Pneumonia by Ice Cradling. I use an ordinary surgical cradle or cradles, made somewhat broader than is usual, and I attach a tray to each cradle. The tray is made of a light tin frame about 14 inches long by 10 broad, with sides 2 inches deep and pierced with a few holes; a floor for this frame is made by attaching to it a piece of flannel lined on its outside with oiled silk. The tray thus formed, having been lightly filled with ice in small lumps, is attached by means of tapes to the cradle, and suspended over the patient in such a way that, although the floor of the tray is in close apposition with the whole of the abdomen or chest wall, as may be required, there is still no pressure or undue weight on them.

Should there be no abdominal or thoracic indication for the application of ice to the patient's body, the tapes are shortened, when the tray or trays will then be suspended over the patient's body in much the same way as Dr. Fenwick's ice palis; and by throwing over them a light sheet a constant current of cooled air will surround the naked or lightly clad patient, and his temperature be kept thereby in check.

In cases of enteric fever, when we have abdominal distension or any appearance of blood in the stools, I invariably employ the ice trays closely apposed to the abdomen in the manner I have described. The advantage I claim for this modification of ice cradling is that with one apparatus we have the means of either surrounding our patient with cooled air, or of applying to his body an iced poultice, as the nature of his case may require.

VARICOSE ANEURYSM FROM A STILETTO WOUND.

DR. W. WILSON (Florence) writes: Professor Colzi, the distinguished chief of the Surgical Clinic at the Sta. Maria Hospital of Florence, had under his care a man, aged 37, with a traumatic varicose aneurysm between the left vena innominata and the arch of the aorta, produced by a wound from a stiletto, perforating both vessels at the same moment. The wound was followed by profuse hemorrhage and insensibility. He was confined to bed for a month, and the wound healed by first intention; four months later, having resumed work, the left side of the face and left arm began to swell. Two years later there was a dark red discoloration of the parts in the same localities, and shortly afterwards non-pulsating exophthalmos; the veins also in the superclavicular region and on the anterior superior part of the thorax became pulsating and dilated. On auscultation there was a thrill over the sternum, continued along the course of the internal jugular, left axillary, and brachial veins, which could also be detected along the cranial sinuses. On December 10th, 1894, eleven years after the injury, the patient was seized with thrombosis, followed by apoplexy and death. The post-mortem showed acute cerebral oedema; the vena innominata was distended, forming a sac the size of an orange, communicating with an opening of about 7 mm. in the arch between the innominata and the origin of the left carotid. The fact of a man living for so many years and following his ordinary occupation is extraordinary and the nature of the accident so singular that the writer is unable to find any record of a similar case, and would feel greatly obliged for any assistance in further search.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	£0 4 0
Each additional line	0 0 6
A whole column	1 17 6
A page	5 5 0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage-stamps.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Prestantes* addressed either in initials or numbers.

AN ADDRESS¹ ON OVARIAN HERNIE, AND THE PROTRUSION OF THE APPENDAGES THROUGH RUPTURE OF THE VAGINAL WALL.

By JOHN WARD COUSINS, F.R.C.S., M.D.LOND.,

President of the Council of the British Medical Association, and Senior Surgeon to the Royal Portsmouth Hospital.

[ABSTRACT.]

GENTLEMEN,—Ovarian displacements are of various kinds. Sometimes an ovary is protruded in the inguinal region, either above or below Poupart's ligament. When it is displaced in the groin it occupies the position and exhibits the appearance of an ordinary inguinal hernia. Occasionally it is found in the sac of a femoral hernia; an ovary is often displaced within the pelvis backwards and downwards into Douglas's space; when lodged behind the uterus it can be recognised by vaginal or rectal exploration as a small and elastic swelling filling the recto-vaginal fossa. Occasionally the vaginal wall is ruptured, and the appendages are protruded into the vagina or even appear externally.

In some cases of ovarian inguinal hernia the displacement is congenital, and arises from a slight error in the early development of the organ. In its descent from the lumbar region it undergoes a considerable change of position, attended by the shortening of a band which corresponds to the gubernaculum testis in the male. Now this band consists of a fold of peritoneum containing involuntary muscular fibres, and it extends downwards from the lower part of the Wolffian body towards the rudimentary uterus, where the ovary is normally arrested in its downward course. Occasionally, however, the organ takes too much the direction of the testis, and by the atrophic shortening of this band it becomes fixed to the skin of the groin which is destined to become the scrotum. Thus, by a slight error, the ovary gets attached a little out of its normal position, and is drawn towards the abdominal ring, and ultimately escapes into the open vaginal process of peritoneum and is protruded into the labium. This form of ovarian hernia is in my experience always irreducible, for the proximal end of the canal soon becomes obliterated.

In the acquired form of ovarian inguinal hernia the protrusion may take place into the sac of an old rupture, and this accident generally occurs soon after labour. Women who have had several children seem prone to this displacement, and I think this can be traced to the relaxed condition of the abdominal walls and the elongated state of the broad ligaments; for the uterine appendages must undergo very considerable stretching before an ovary can find its way into the inguinal canal. The displaced organ is always liable to inflammatory changes, and occasionally it has been known to undergo cystic or sarcomatous degeneration.

Now, as regards diagnosis, an ovary displaced into the inguinal or femoral region presents many of the characters of an ordinary hernia. Whenever it occupies the sac alone, it is usually a small oval and non-resonant tumour, it never gurgles on manipulation, and it does not feel soft or doughy. When of small size it really presents very much the appearance of a swollen inguinal gland.

I do not think it is often possible to recognise an ovary in a hernial sac. Schroeder² states that in one of his cases the diagnosis was remarkably clear. "While the left ovary could be felt lying rather far back but in every other respect normal, nothing resembling an ovary could be found among the uterine appendages on the right. On this side, however, the uterine appendages were drawn down towards the inguinal canal, and in front of them lay a body of the size and form of an ovary in a little hernial sac. This body was only slightly sensitive on deep pressure, and the patient had not noticed that it ever appeared swollen during the men-

strual periods. On grasping it externally with one hand and with the other pushing the uterus backwards and towards the left a decided traction could be exerted upon the body in the hernial pouch; it would slip upwards and outwards from between the fingers which held it, but it could not be drawn through the inguinal canal, nor could it be replaced by external manipulation."

Sometimes the diagnosis has been assisted by changes occurring in the tumour during the menstrual epoch, as the displaced organ may become enlarged and painful from functional activity, and then as soon as the period passes off these symptoms gradually subside. These changes, however, do not always occur in ovarian hernia, and therefore their absence cannot be regarded as conclusive evidence that the protrusion does not contain an ovary. In the following case of acquired inguinal ovarian hernia pain, swelling, and obstinate nausea followed a miscarriage which was attended with considerable hæmorrhage.

C. D., a stout woman, aged 34, was admitted under my care into the Royal Portsmouth Hospital in November, 1894. She was the mother of eight children, and had had three miscarriages. On examination an ovoid tumour, about the size of a small egg, was found in the right groin. The swelling was both firm and fixed, and it occupied the position of an inguinal hernia. She stated that it had never exhibited any enlargement or tenderness at the menstrual period. It had existed ten years, and had never caused her any inconvenience until her last miscarriage, but since that occurrence it had become larger, often very painful, and the slightest pressure excited a sickening uneasiness. On account of these urgent symptoms she was very anxious to have it removed, and at her request I excised the tumour. It contained an ovary, and the sac and its coverings were much thickened by chronic inflammatory changes. On section it exhibited a well-marked corpus luteum. The patient returned to the hospital some weeks after her discharge in good health.

A few words as regards treatment. In ovarian inguinal hernia all efforts at reduction are generally useless. In the congenital form it is impossible to return the organ into the abdominal cavity, as the neck of the sac becomes occluded in a similar manner to the normal closure of the canal after the descent of the testicle. Whenever the displaced ovary excites very little inconvenience surgical treatment is scarcely necessary. If the organ becomes inflamed our efforts must be directed to relieve pain and congestion. I have never seen an abscess occur as the result of acute or chronic inflammatory changes, but whenever this is a sequel it should be treated in the ordinary way by free incision. Herniotomy with replacement may be occasionally possible in recent cases of acquired hernia. When pain and swelling are distressing at the time of menstruation, and the patient becomes a chronic invalid, excision is the only remedy. Occasionally an ovary, like a displaced testicle, may undergo sarcomatous or malignant degeneration, and under these circumstances early operation would be the only hope of relief.

The treatment of displacement of the ovary into Douglas's space is often a very simple matter, and in a large number of cases the symptoms can be greatly relieved by rest in the prone position, attention to the action of the bowels, and the application of a well-adjusted pessary. This displacement is sometimes associated with other serious disorders, such as an ovarian tumour, a uterine fibroid, or a chronic malposition of the uterus. Whenever the organ is the seat of hopeless structural change, and is exciting both local and constitutional trouble, surgical treatment is absolutely necessary.

RUPTURE OF DOUGLAS'S POUCH AND PROTRUSION OF THE APPENDAGES.

Prolapse of the abdominal or pelvic viscera through a rupture of the vaginal wall is a very uncommon accident, and is scarcely referred to by any English writers on gynaecology. In all the recorded cases this laceration has been associated with some abnormal condition which has weakened and stretched the vaginal wall. The small intestine and the uterus have been prolapsed through a vaginal rent, and in the case I shall briefly narrate, the appendages were suddenly protruded and strangulated.

Brosky³ states that spontaneous rupture of the vaginal

³ Billroth and Luecke, *Deutsche Chirurgie*, II. 65, 2. 90.

wall occurs almost exclusively during labour. A few cases only have been recorded as occurring under other circumstances. Grenser has reported a case in which in a pregnant woman suffering from ascites the retroverted uterus, which was the size of the fist, passed through a rent in the posterior vault of the vagina, and became prolapsed through the vulva. Death in this case was hastened by surgical interference. In another case (Samples) rupture of the posterior vault of the vagina occurred three months after parturition. A finger could be passed through the rent into a cavity which did not communicate with the peritoneum. The rent was closed with a couple of sutures and the patient got well. Broisky agrees that it is probable that the rupture in this case was due to the bursting of a hematoma. In another case reported by Fehling, the woman, who was 63 years old, and had had 11 children and 1 abortion, had been in the habit of forcibly replacing a prolapse, which had existed for fifteen years, when it was brought down by exertion. In this case there was rupture of the posterior vaginal wall and prolapse of intestine. Rokitsansky recorded a case in which a similar accident was found *post-mortem*, but there was no clinical history.

I am indebted to Mr. Alban Doran for this reference and to Dr. Brunton, the assistant medical officer at the Asylum for the following notes.

Diagram showing the protrusion of the appendages externally.
A Rectal prolapse. B Uterus. C Uterine appendages.

L. B., aged 50, a tall and cachectic-looking woman, and the mother of several children, was admitted into the Portsmouth Asylum, under the care of Dr. Bland, in October, 1893, suffering from melancholia. Shortly after admission she was found to be labouring under severe prolapsus of the uterus and rectum. The uterus was completely prolapsed, and appeared externally like a large sausage-shaped body covered by the vaginal wall. The rugæ were all effaced, and some abrasions existed on the cervix. The rectum protruded about 4 inches, and was marked by many superficial ulcerations. Both organs were reducible by manipulation, but no amount of mechanical support was sufficient to retain them in position for any length of time in consequence of the persistent straining of the patient.

A few weeks after admission the attention of Dr. Bland was called by the nurse to a large swelling that had come

down during the night. On examination, a fleshy and irregular mass was discovered protruding from the vulva directly behind the prolapsed uterus. On December 29th I was called in to examine the case. The protrusion was found to be an ovary and tube in a condition of acute strangulation, which had escaped through a laceration of the vaginal wall. The patient was in a state of great depression and her pulse was quick and feeble. She complained of great pain, and occasionally vomited. The protruding organs were returned at once, the mass was pulled down, secured at the neck by a ligature, and then cut off. The vagina was wiped dry, dusted with iodoform, and a gauze plug inserted into it. During the after-treatment the patient gave a great deal of trouble by tearing off the bandages; her habits, too, rendered it impossible to maintain local cleanliness, although antiseptics were constantly used and the vagina was assiduously wiped out with iodoform.

The protruded organs fortunately gave very little trouble. Two weeks after the operation a little vaginal hæmorrhage occurred. By the end of February the patient had made a good recovery. She is still under treatment. Her mental condition has not improved, but neither organ has been protruded externally for many months.

In this singular case the uterine and rectal prolapse must be regarded as the primary cause of the laceration. The patient, in a state of mental derangement, gave way to violent and persistent expulsive efforts, which greatly tended to stretch and weaken the pelvic structures. During a fit of straining the rupture occurred, and the uterine appendages, including one ovary and tube, slipped out at once through the rent in the vaginal wall. At the time of the operation the protrusion was in a state of acute strangulation bordering upon gangrene; it was deeply congested and thickened, and presented some resemblance to a placenta. The safety of the patient was fortunately secured by adhesive peritonitis around the seat of laceration.

PRESIDENTIAL ADDRESSES

DELIVERED AT THE

ANNUAL MEETINGS OF THE BRANCHES

OF THE

BRITISH MEDICAL ASSOCIATION.

RATIONALISM IN THE STUDY AND PRACTICE OF PHYSIC.

Delivered at the Annual Meeting of the Birmingham and Midland Counties Branch on June 18th, 1895.

By ALFRED H. CARTER, M.D. LOND., F.R.C.P.

Senior Physician Queen's Hospital, Professor of Therapeutics Mason College, Birmingham.

[ABSTRACT.]

GENTLEMEN,—By "rationalism" I refer not to any doctrine or set of doctrines, but to an intellectual temper, a mental attitude which recognises a right and a wrong way of approaching even the simplest things and nourishes the desire to take the right way, or at least to avoid the wrong way, though at the risk of temporarily standing still. It is a mental temper in which the results of observation are submitted to the crucible of reasonable reflection with a view to eluce some general principle—some general truth or law. Rationalism is, in short, the exercise of common sense in an uncommon degree. Science without common sense amounts to nothing more than vain and barren scholism. But so long as we bring to bear a shrewd common sense upon the examination of our patients the observation of signs and symptoms and the interpretation of the disturbance on which they depend, and so long as we exercise the same common sense in the selection of remedies, with the effects of which we are daily becoming more familiar, we may claim that our methods are as rational and scientific as those of the student of astronomy, geology, or chemistry.

Again, it is said that medicine is inexact. But I contend that the conclusions or facts of anatomy and biology, on which

the superstructure of medicine so largely rests, are as exact in their way as those of mathematics, and the statement is equally true of medicine itself. If the charge of inexactness when applied to medicine means nothing more than that many of its laws are still imperfectly worked out, and that many of them are as yet altogether unknown; or if it means that by reason of the complexity of its subject matter and the number and variety of interfering conditions we are in many cases only able to forecast with approximate probability the results which will occur under given conditions, it is a charge which is applicable in a greater or less degree to every science known to man.

The methods of all sciences are the same, and consist of (1) observation, (2) comparison and classification of observations, (3) generalisation, and (4) verification; and it is no figure of speech to assert that the methods of modern medicine conform to this test in all essential respects. Let us take typhoid fever as a single example. Simple observation teaches us that in the presence of defective drainage a continued fever is apt to occur, which can be rigidly distinguished by signs, symptoms, and anatomical lesions from all other febrile disorders; we observe that persons living outside the insanitary area may be attacked, if allowed to drink water which flows from it or near it; and, lastly, we observe that the disease is liable to be communicated by those entering from it to healthy persons, if the former are not kept scrupulously clean, and especially if not kept free from abdominal contamination. So much for observation. Then by comparison and classification of our observations we arrive at the following conclusions: (1) That the fever is due to some definite cause associated with defective drainage; (2) that this cause is something which can be carried about in water; and (3) that probably it has some definite relation with the defects of those already stricken with the disease. Finally comes the verification, when on the occurrence of several cases in different places at the same time, under a variety of conditions, with the only discoverable agreement in the fact that they have all partaken of milk supplied from the same source, served in vessels which have been washed out with water tainted with sewage.

A contrast is often drawn between rational and empirical medicine as if they involved a natural antithesis. As a matter of fact, empiricism in its best sense, such as occurs for instance in making a carefully balanced comparison between the effects of remedies upon a given disease and the results obtained by using other remedies, or by leaving the disease in question to take its own course, is not by any means opposed to reason or common sense, and has in many instances been productive of most fertile additions to our stock of organised knowledge. All science takes its origin in empiricism; and between purely empirical facts on the one hand and facts having a definite scientific basis on the other we meet with every degree of certitude.

The whole fabric of rational medicine rests upon a tripod, of which the one division is clinical observation and study of the signs and symptoms of disease; the second is the study of the nature and processes of disease; and the third is the study of remedies employed for the relief and cure of disease.

Of the three, clinical study is the natural antecedent of the other two, and is at the same time the most ancient, dating its origin from Hippocrates, 400 years before the Christian era. He it was who first prepared the way for the rational study of medicine, by separating the pursuits of the physician from those of the priest and philosopher, with whom it had previously been inseparably identified. He overthrew the doctrines which referred diseases to the malign influence of angry gods, and struck the keynote of rational medicine by declaring that no one disease was more divine or human than another, and that none arose without a natural cause. From this starting point he set himself seriously to observe the signs and symptoms of disease with surprising detail and precision, paying particular attention to their mode of evolution. Such doctrines as Hippocrates adopted in order to give cohesion and definiteness to his practice are often unusual and erroneous; but he never strongly urged them upon others, and, beyond insisting upon the importance of waiting upon Nature and assisting her in the process of recovery, he nowhere seems to regard his doctrines as more than provisional hypotheses.

The very intellectual strength of Hippocrates as a physician was a source of weakness in the promulgation of his teaching after he had passed away. The spirit of his methods was so far in advance of his age that it was difficult for anyone to follow exactly as he had led. But this is not all. Hippocrates knew no anatomy or physiology; his generalisations rested on no experimental or scientific basis; and therefore, wise as were his precepts, and excellent as was his practical common sense, his teaching lacked just that measure of rationalism which was necessary to ensure its persistence after his death. When the memory of the master grew dim his followers began to split up into sects, many of which entirely threw off his authority. Among these sects there are three to which just a brief allusion must be made: the dogmatists, the empirics, and the methodists. The first were nearest to the Hippocratic model in the importance they attached to the discovery of the causes of disease. The aim indeed was excellent, but in the heat of their desire to establish causes at any price they attempted to build where there was as yet no solid foundation, and to make up for what was wanting in fact by the incontinent employment of their imagination. Are there no dogmatists nowadays? I think there are, and the hindrance which they oppose to the progress of scientific medicine is especially difficult to meet because, owing to the increasing complexity of the problems to be solved, the nearer we get to the final causes of disease, and owing to the technicalities which surround their solution, criticism is necessarily confined to the few, and the results obtained by accredited observers are apt to be taken too much upon trust.

The empirics repudiated all concern with the causes of diseases, and taught that they were to be judged by their symptoms alone, and thus reduced the whole of medicine to questions of treatment, occupying themselves with an endless search for specific remedies. They existed as a separate school for some centuries, and then split into two branches—the one philosophical, culminating in sceptic agnosticism; the other practical, culminating in an apotheosis of the wildest credulity. Empiricism of this kind is with us to-day, leading as before to scepticism and credulity. Nor is it surprising; for, though much of it is probably due to ignorance or idleness, yet we must not ignore another cause, arising from the inevitable fact that the actual demands made upon us all in our daily work of ministering to the needs of the sick are always largely beyond the limits of precise knowledge.

The methodists strained after a pseudo-simplicity by referring all disease to one or other of two groups, according as they were attended with constriction or relaxation of the "pores," to which corresponded a dual system of treatment, on the principle of *contraria contrariis curantur*—namely, by laxatives (bleeding, cupping, and leeches) or astringents (cold air and water, vinegar, and certain mineral substances) respectively. They disclaimed anatomy, regarded all diseases as general in their nature, and deemed it quite unnecessary to learn their remote causes. This was simplicity at all costs, and it was the boast of one of their most eminent partisans—Thessalus, of Tralles—that he could teach the whole system to anyone in the course of six months. The methodists also have their representatives to-day in the school of homœopathy, in so far as it is still practised conformably to the teaching of its founder. Homœopathic methodism, on the one hand, assumes to have brought the entire cure of disease under the operation of a single law—that like things are cured by like—a law which stands quite outside any considerations with regard to the causes of disease, claiming perfect simplicity and perfect safety; while, on the other hand, homœopathy excludes within the limits of its application every possibility of failure and condemns every system other than its own.

Fydenham revived the Hippocratic method in basing his practice almost exclusively upon clinical observation. "The improvement of physic," he says, "depends upon collecting a generic and natural description or history of all diseases, so far as can be secured." If he had confined himself to this his influence would possibly have been greater than it actually was; but unfortunately he greatly exaggerated the importance of searching for specific remedies, and his well-known doctrine of "epidemic constitution," which he bas-

rowed directly from Hippocrates, was distinctly harmful, by relieving the practitioner from all responsibility in troubling about investigation in the presence of influences entirely beyond his control. On the whole, however, the influence of Sydenham's teaching was bracing in the extreme, and was ably developed by Baglivi in Padua and Boerhaave in Leyden. No praise is too high for the zeal with which Baglivi attacked the prevailing tendency to system making, nor for the luminous simplicity and strong common sense of dear old Boerhaave.

It is astonishing how history repeats itself. As with the teaching of Hippocrates of old, so with that of its glorious triumvirate. It was unable to resist successfully these philosophic tendencies which formed so striking a feature of the eighteenth century. Attention was diverted from clinical observation and study by the animism of Stahl, the vitalism of Barthez, the organicism of Haller, and the methodism of John Brown, in succession. In spite of all this, the silver thread of clinical research was not utterly broken. Auenbrugger, a junior physician at the Vienna Hospital, had published in 1781 a small pamphlet on "A New Invention for discovering Obscure Thoracic Disease by Percussion of the Chest," but its importance was never recognised until it was unearthed and brought into prominence by Corvisart, in 1828, which date marks the effective birth of the art of percussion. Eleven years later Laennec invented the stethoscope, and gave to the world his epoch-making treatise "On Mediate Auscultation." By these new methods of investigating disease at the bedside, and the interest which they aroused, an enormous impetus was again given to the progress of clinical medicine—a result which has since been repeated over and over again by the discovery of fresh instruments of clinical research. By these means, not only has the extent of clinical knowledge been greatly increased, but it has attained a degree of accuracy which probably never entered into the wildest dreams of the mighty clinicians of the seventeenth and eighteenth centuries.

The central and primary idea which underlies pathology as applied to practical medicine is essentially anatomical. *Ubi est morbus?* as Virchow so eloquently argued in his address to the International Congress at Rome, is the question with which every examination of a living patient must begin. To Morgagni (1761) belongs the honour, in his memorable work, *De Sedibus et Causis Morborum*, of being the first anatomist to insist upon the fundamental importance of this question to the practitioner of medicine; and he himself went a long way to provide the means of giving a correct answer to it, thus laying the foundation of morbid anatomy, and bringing it into closer association with practical medicine than it had ever been before. After his time the search for the true localisation of diseases was carried by Bichat from the organs to the tissues; and still later, by Virchow, from the tissues to the cellular elements of which they are built up.

But it is not enough to be able to tell the seat of disease and its likely termination, important as these questions undoubtedly are. We have to recognise the fact that disease is a process, to find out as clearly as we may the nature of the process, and to work out as far as possible the chain of causation involved in the process. It is also obvious that a knowledge of perverted bodily processes must be preceded by a knowledge of the same processes in a state of health. Before Harvey's time physiology can scarcely be said to have existed. His discovery of the circulation of the blood produced nothing short of a revolution in the attitude of medicine to the vital processes of the body; but, at the same time, his general conception of their nature was little, if at all, in advance of those who preceded him. The steps by which the modern position was arrived at are briefly these. Descartes, in the seventeenth century, was the first to regard all the properties of living matter as purely physical. In their nature, looking upon the body as a mere machine actuated by some central source of power, like the mechanism of a watch. Then came Stahl, who ascribed all vital processes to the working of the soul. Next was Barthez, who attributed them to a central vital principle; and then Haller, who took an important step forward by recognising that the processes of the living body represented the processes of the living parts of which it was built up. This doctrine was still more clearly and definitely expounded by Bichat, who says: "All

animals are assemblages of different organs, each of which performs its functions, and concurs, after its fashion, in the preservation of the whole."

The latest addition to rational medicine consists in the systematic efforts which are now being made, and with considerable success, to ascertain the actual effects of remedies upon the body, with a view to our guidance in their selection, and in the application of them to the treatment of disease. The study of pharmacology is yet in its infancy, and the larger part of our practice is still purely empirical; but it has already profoundly influenced the attitude of the practitioner in the employment of remedies.

Where so large a portion of our practice is empirical, it is impossible to lay down universal principles for guidance. There are some general rules, however, to which I attach special importance. (1) In the front rank I place the Hippocratic maxim, "to do good, or to do no harm." (2) The treatment of causes should take precedence of the treatment of symptoms; and with this end in view the investigation of causes should be pushed back as far as possible. (3) In the treatment of symptoms, precedence should be given to those which most obviously hinder any natural tendency to recovery. (4) No active remedies should be used without a distinct conception as to the indication they are selected to meet, not without some definite idea as to what is expected from their employment. (5) In dealing with serious disease, a reliance as far as possible to remedies with which we are familiar. (6) The importance of simplicity in the selection, prescription, and administration of remedies.

The circumstances of our time are by no means uniformly favourable to the interests of rational medicine. There are two, especially, of which I should like to say a word or so. The first is over-work, by which I refer to an obligation to deal with a large number of cases in a space of time, which makes it impossible to go properly into each. Our hospital and dispensary out-patient departments afford striking illustrations of this. As a result of overcrowding, it is out of the question to give to every case the attention that it requires, and personally I entertain no doubt as to the demoralising influence which out-patient practice—conducted under these conditions—has upon those who engage in it. It accustoms the medical officer in charge to a superficial and haphazard way of practice, and familiarises the student with an example which is most pernicious. Fortunately, in our medical schools the worst results are to some extent obviated by the selection of a few suitable cases for special examination and study, and also by the example of the better methods pursued in the in-patient departments. Similar remarks apply to club practice and parish practice on a large scale, and in a tenfold degree to those abominations known as medical aid societies. Here, however, there is not only the element of over-pressure, but that of under-pay. The weight of remuneration is so woefully low that it is not in human nature to expect that men practising under such conditions are able to do justice either to themselves, their patients, or their profession. It is easier to state the evil than to find a remedy; but nothing can be conceived which is more inimical to the interests of rational medicine than the circumstances to which I have referred.

Another unfavourable influence arises from certain defects in the present system of medical education. So long as the curriculum is crowded with subjects, and with examinations in ever-increasing number, even the best students experience the greatest difficulty in obtaining a firm rational grasp of their work; while the majority are sorely tempted to give up all honest work in despair, and trust implicitly to the "tips" of a crammer and the indulgence of a beneficent Providence. When rational methods of thought and study are thus neglected from the outset they are more often never afterwards acquired.

The remedies for this evil lie largely with the examining Boards. In the first place there should be one uniform preliminary examination compulsory for all, which should be a real trustworthy test of a candidate's intellectual capacity, instead of requiring nothing more than a mere smattering of some half-dozen subjects. Speaking as a teacher of considerable experience, I do not complain of want of ability in the students who come under my notice, but rather of the lamentable absence in so many of them of any kind of exact-

ness or method in their habits of thought and expression. Of course this is traceable to defects in the prevailing system of middle-class education; and I believe, with Mr. Goschen, that the fault is due in large measure to the fact that our upper-class education has been framed in accordance with the wants of a section of society which has no need to work, and that this example, which has been set in the highest educational plane, has made itself felt down to the lowest.

Again, the knowledge that a student is required to pass of chemistry, physics, and elementary biology should be obtained, and the examinations in these subjects should be passed before he is permitted to register; while materia medica might be altogether eliminated from the curriculum with positive advantage and relief, both to teachers and taught. It is also very doubtful whether, in view of the heavy demands made upon a student, if he works as he ought, systematic lectures on medicine and surgery are really necessary. I believe that the fees expended in this direction would be much more profitably employed in maintaining professorships of clinical medicine and surgery, to conduct frequent systematic demonstrations of disease at the hospitals, in which the students should personally take part, and from whom written reports and commentaries of cases should be periodically received for correction. A plan of this kind would have the advantage of bringing the teacher and students into more intimate personal contact, the work done would be more attractive, with the further advantage of recurring continually both in the substance and style of teaching.

Owing to the short time at their disposal students cannot expect to obtain a large experience. Their object should be rather to lay up a store of useful general principles by the rational and scientific study of a small amount of carefully selected material, which will be the best possible foundation for the practical experience of the future to rest upon. The modest and highest ideal for teachers is not to load students with a mass of detailed information, however sound, nor with long strings of empirical maxims, however shrewd, but to develop in them an intellectual capacity, and to inspire them with an intellectual interest, which will enable them to go through life teaching themselves. This, in my opinion, can only be done by a vigorous endeavour to make our teaching above everything intelligent, suggestive, and rousing, and by trying to place all we do or say upon as rational and scientific a basis as the state of knowledge permits.

I wish to lay especial stress upon the intellectual interest which belongs to and is an inherent feature of rational methods of work. There are other interests—the interests of success, ambition, profit, and duty, for instance—which, valuable as they often are as incentives to undertake our work and to persevere in it, yet, after all, are external to work, while intellectual interest takes its origin and grows in the work itself. External interest leads us to undertake work for what we can get out of it, while intellectual interest leads us to work for the sake of the work itself.

There are many who care little or nothing for laws, principles, or general truths, whose best it is that they are above everything practical men of affairs; and it is doubtless true that, with vigorous energy, good natural ability, and native shrewdness, such men often command great success, in the usual sense of the word. But, at best, they only serve themselves; their success dies with them; they have nothing which they can impart to others, and have done nothing to broaden the foundations of their work or to lift it on to a higher plane. On the other hand, the man who works from intellectual interest serves others as well as himself. He leaves behind him general principles and truths which not only enrich the common stock of knowledge at the time, but give stability and guidance to all who come under their influence.

I do not pretend for one moment that the whole duty of medical life is summed up in rationalism, be it never so thorough. All the rationalism in the world, by itself, will not make a man a good doctor; but if he has in him the making of a doctor at all, rationalism will give life to his work; it will give him keen pleasure in his work, and will forward the work of others in the same calling as himself.

I have only dwelt upon the subject of rationalism as I should the purely professional side of our work, but unless I am much mistaken there is ample room for the wider applica-

tion of rational methods into the commercial side of medical life and practice. On this and other phases of my theme I should like to have touched had time permitted.

I have undertaken to show that modern medicine can claim a rational and scientific basis. I have indicated the more important historical steps by which this result has been attained, and I have pointed out one or two of the unfavourable influences with which rational medicine has still to contend. Rational observation and study have immeasurably extended the range of our knowledge, revealed many new truths, and practically created preventive treatment of disease. But above all they have made us free, emancipated us from the thralldom of dogma and the chains of orthodoxy. Such, in brief, is the conquest of rationalism. It does not belong to any one man, to any one country, to any one race, or to any one epoch. It is still in progress, and the full fruition of it has yet to be won, and may be long delayed.

A HISTORICAL SKETCH OF THE PHYSICIANS AND SURGEONS OF THE NORTHAMPTON INFIRMARY IN THE LAST CENTURY.

Delivered at the Annual Meeting of the South Midland Branch at Northampton on June 25th, 1906.

By ARTHUR H. JONES, M.D. Lond., M.R.C.P.,

President of the South Midland Branch; Physician to the Northampton General Infirmary.

[ABSTRACT.]

Dr. Jones prefaced his address with a few remarks in eulogy of those who had preceded him in the presidential chair. He reminded his auditors that in the fifth year of the Branch Dr. Francis, then its President, detailed the history of many of the physicians connected with the town of Northampton. Dr. Jones then proceeded to say that of the physicians and surgeons attached to the Northampton Infirmary none, perhaps, was more distinguished than the founder of the institution, Sir James Stenhouse. His coming to the town was in the days when Northampton wore its early beauty, before the modern factory and other disfigurements had robbed it of so many attractions. "It is on the whole," says a cartographer in 1742, "one of the most elegant towns and delightful situations in Britain, and is surrounded with a greater number of gentlemen's seats than are to be found within an equal distance of any other market town in England so far from London." In the portrait of a divine over the mantelpiece you will perhaps hardly recognise a professor of the healing art. But this remarkable man, who commenced his career as the popular physician, ended it as the popular patron of fashionable Bristol. Such phenomenal success is seldom attained as Stenhouse achieved. Being but 26 years of age when he came to the town he was prepared to wait for practice, but fortune favoured him, and by the death of Dr. Freeman, his learned and skilful predecessor, he suddenly found himself a prosperous man. In a few months his influence had so increased that he was successful in gathering around him all the nobility and gentry of the county, to found the infirmary, while in the following year he was so well established that the poet Akenaide, with all his ability, was not able to share with him the emoluments of his work.

He owed his popularity to his affable and polished manners and his brilliant and instructive conversation. His unbounded interest in infirmary affairs gave him great influence in the management of that institution. His aggressive deism, for such were his opinions on coming to Northampton, soon made him enemies, and his vulnerability lay in his impetuosity and imprudence, which none of his friends could restrain. The storm of opposition bore around him in the committee-room of the infirmary in the autumn of 1745, when he was openly charged with having "rid the gentlemen of the county for three years past," on an attempt made to expel him. This only just failed of success through the judicious interference of his close friend Dr. Doddridge, to whom he was indebted for many acts of kindness, and not the least that he was the means of leading him to abandon the atheistic views he had imbibed from his former master, Dr. Nisbet.

This remarkable man was at some time or other at various

with nearly all his colleagues. If the present tendency of professional criticism in the medical world is for the surgeon to be scandalised, if the physician soils his fingers by the catheter or such like minor operation, the reverse obtained 150 years ago, when we find Stonhouse advocating before the committee the creed then maintained (the physicians as a body) that "it was irregular for a surgeon to prescribe internal medicines and that if Mr. Lyon" (his surgical colleague and mayor of the borough) "was still allowed to do so," he would resign, "lest he should render himself contemptible in life and so obnoxious to all his brethren in the profession, as, if he permitted things to go on in this channel he must necessarily become." And what was Lyon's offence? He had operated on a case of fistula, and then prescribed for a subsequent diarrhoea. The house apothecary, according to his instructions, had refused to dispense the remedy, and he had therefore "sent it from his own shop." That this practice was *ultra vires* is proved by the verdict of Mr. Ford, then surgeon at Bristol, which was emphatically against Mr. Lyon. So different was the status of the surgeons in those days. It will be remembered that this occurred just at the time when the surgeons had advanced their position by separating from their union with the barbers to form a company of their own.

The causes of Stonhouse's disputes with his other colleagues are happily unrecorded, but matters proceeded to such extremities that the Committee had them "pursue the business of the hospital without pique or rancour," distinctly threatening that any one of them against whom "a complaint might be made or misbehaviour proved" should be reported to the general court as "incapacitated from the service of the hospital."

Of Stonhouse's scientific and professional achievements there are no remains. His published writings, though many of them belonging to the early days of his medical career, are of the nature of religious tracts, which passed through many editions. His later career as a preacher was as honourable as his earlier one, and his influence and popularity in no way lessened.

It is interesting to trace the origin of the Leicester Infirmary to one of the physicians of our own hospital. Dr. Watts—himself a Leicester man—practised here from 1757 to 1762, when he returned to the neighbourhood of his native town, and, after a four years' struggle with opposition and misunderstanding, founded a similar institution to our own, amid the plaudits of those who rallied round him. He is said to have been "a man of philanthropic aims and persuasive eloquence. In friendship few exceeded him; in benevolence none." This physician also appears to have had some connection with the sister profession, for an ode to him as founder of the Leicester Infirmary is inscribed "to the Rev. Dr. Watts."

Dr. Anthony Fothergill¹ was a learned and scientific man. Dr. Lettison, the well known genius of the Medical Society, described him as "one of the most amiable of men," and our own Sir James Stonhouse considered him "one of the best physicians in England," to whose hands "he should entrust his life." He has no doubt been often confounded with the famous Dr. John Fothergill, the Quaker. There was no relationship between them, but it was by John's advice that Anthony settled in Northampton, and the senior very considerably encouraged the younger man during the ten years which passed before any satisfactory amount of practice came to him. In Northampton his scientific bent had many opportunities. The severe frost of 1766, during which Fothergill made sundry observations, furnished material for a paper to the Royal Society, of which he was later elected Fellow. Vapour baths and electrical apparatus at the infirmary underwent improvement during his time. The foul air in the wards of the old hospital in George Row supplied him with a sphere of investigation for which the governors supplied the appliances.

Frostley's discovery of oxygen, then called phlogistic air, which occurred so aptly during the early enterprise of the Royal Humane Society, set Fothergill experimenting and

theorising. His essay on apparent death dealt with the function of respiration and the application of the facts known, to the restoration of persons drowned and suffocated. This essay secured the prize of the Society. In it he advocated the supply of pure oxygen to law courts and other public buildings, as a valuable means of promoting ventilation. Stoves were to become much more effective under the influence of the same gas. The most remarkable suggestion was that at the stations of the Royal Humane Society glass jars containing oxygen should be stored inverted over lime water, for the restoration of drowned persons. What interest he would have felt in our present method of storing in cylinders and the use of oxygen in pneumonia following influenza, for which latter he himself proposed its employment. An amusing narrative *apocryph* of the value of agitating the body of an apparently drowned person, occurs in his prize essay, and cannot be better told than in his own words:

A remarkable instance accidentally occurred some years ago at a funeral procession, when a sudden jolt of the hearse is said to have disturbed the repose of the apparently dead lady within, who, to the surprise of the attendants and utter confusion of her husband, instantly gave a piercing shriek. This being repeated in the usual shrill and well known key, left him no room to doubt of his care soon being still attended to. It therefore obliged him, though very reluctantly, to put an end to the funeral ceremonies, and release the supposed corpse, who, it is added, lived many years after, till at last she had the satisfaction of seeing the husband peacefully inured near the very same spot.

The Bath and Cheltenham waters which he analysed furnished material for another pamphlet. The Japanese filtering stone, which had been advocated as an absolute preventive of gout, gravel, and rheumatism, provoked his amusing satire. "What joy and triumph," he writes, "will it not afford thus at once to deposit their gout and stone and bid a lieu to their nurses, crutches, flannels, and other disagreeable accoutrements! What unspeakable pleasure to triumph over their doctors and apothecaries—to rally them on their ignorance, and finally to put them for ever after at defiance! But they must put on their spectacles and sift the affair more closely, and they will find with grief and astonishment that the morbid particles of gout and stone are too subtle to be caught, and the Japanese have been too hasty in their conclusions."

Leaving Northampton, he made a futile effort to succeed his namesake and patron in London, then went to Bath, where he had an extensive practice. On his demise, at the age of 77, he proved the success of his career by the amplitude of his fortune and the extent of his bequests, amongst which were a sum of money to the Medical Society of London for the Fothergillian medal and £200 to the Northampton Infirmary.

Northampton has furnished its quota to the line of specialists in the person of Dr. Robert Bue, who, being disappointed here, in 1783 repaired to Leicester. Unfortunately his success was interrupted by severe asthma, which compelled him to relinquish the practice of his profession. The value of open air occupation with abundant exercise in the treatment of this malady is well illustrated by his experience, for, after three years' constant employment in attending to the duties of captain of a militia regiment, he fully regained his health and resumed practice at Birmingham.

He contributed to medical literature a work on the disorders of respiration, which was considerably in advance of any then extant, and contained the narrative of his own case. The patronage of the Duke of Sussex, a fellow sufferer from asthma, led to his migrating to London, where he held an honourable position and gained an extensive practice.

The most obvious case of unappreciated genius in the list of our physicians is that of James Curry. For five years and four months he sought to win the notice of the inhabitants of Northampton, then in despair concluded, as Bue and others had done, that to attempt to cope with Kerr's rising popularity was vain. At first he turned to Kettering, but the rejection at Northampton was soon followed by promotion, on March 10th, 1803, at Guy's, where he became one of its most distinguished physicians. Zealous as a student to the degree of permanently impairing his sight by burning the midnight oil, he won the praise of the governors of our infirmary for his regularity and attention to his duties, while his colleagues and successors at Guy's could not speak too warmly of his ardour, acuteness of mind, and brilliant talent.

¹ Born at Sedburgh. Graduated M.D. Edin. October, 1766. He visited America after leaving Bath, but returned home a year before his death, which occurred on May 11th, 1810. He is buried at St. George's Church, Barry.

Curry recognised the duty of every man to help his brother in emergencies, but this involved matters which the popular mind regarded as beyond its ken, a long cherished superstition, perhaps too jealously fostered by the profession. His first work written for the Northamptonshire Preservative Society, a branch of the Royal Humane Society, dealt with the means of restoring the apparently drowned and other modes of rendering "first aid." Although his methods were crude and clumsy, they were a step in the direction of that later ambulance movement which now promises to prove a valuable aid to the beneficent work of our profession.

Curry displayed some amusing eccentricities. He had a strong belief in calomel and its universal application. With him there was only one organ diseased—the liver, and only one medicine prescribed calomel. Curry roundly claimed, when confronted at the *post mortem* examination with an apparently healthy liver, that he had cured it with calomel. This led of his gave rise to the allegation that he took sandwiches in his carriage which he sprinkled with calomel, and won for him the sobriquet, "Calomel Curry."

His other eccentricity was in extraordinary contradiction of his usually penurious habits. He would frequently visit auction sales, and purchase books, scientific instruments, electrical apparatus, and such like which, once delivered at his house, were simply stowed away and never unpacked. He appears to have been a most unfortunate man as far as his personal health was concerned. A painful ophthalmia, which in a paper he read to the Medico-Chirurgical Society he described as remittent, was a constant hindrance to him, and once subjected him to Dr. Kerr's lancet, while it necessitated the wearing of those broad-brimmed spectacles which give him so knowing a look in his portrait.

I must not venture to cross the threshold of the present century in my sketch of our predecessors, and therefore must part company with the physicians, only wishing that I had time to tell of Robertson, once president of the British Medical Association at its annual meeting in this town, who figures in literature as the physician from Northampton in *Tom Brown's School Days*; of Kerr, nephew of the first of that name; of Francis, the cautious and refined, whose work on climate, especially that of Spain, may still beread with interest. The list of physicians is a long one owing to the fact that so many resigned the task of competing with Kerr; but the surgeons were not many. This was partly due to Kerr's monopoly, but partly to the long lives that many of them lived.

Of Alderman Lyon I have already spoken. His senior colleague, Mr. Litchfield, who was long connected with the infirmary, is practically unknown to us. The *Mercury* of 1745 contains a curious advertisement in which a gentleman named Daventry, who had been a patient of Litchfield's, seeks to dispel the idea which had gained publicity that his charges were extortionate. I do not think that any member present will regard 25 guineas as an extortionate fee for the senior infirmary surgeon to charge for amputation of the leg and more than thirty visits afterwards to Preston-on-the-Hill near Daventry.

Fabian, on the pretext of silencing calumny, boldly advertised that he would deliver any woman for two guineas in Northampton, or three guineas within five miles. Further he would cut for the stone at reasonable fee and search for it for one guinea and a half. One David Bull, who removed to Northampton from Oxford, followed the next month with midwifery fees at half the rate, and further declared that he had restored people the use of their limbs in one tenth the time taken by other country practitioners, seldom confines patients to their beds for fracture more than seven or eight days, and never wounds the rectum in cutting for stone. That Dr. Kerr should have allowed the committee to insert a paragraph in the paper stating that a patient of his had been discharged perfectly cured after cutting for stone in 1794 is a further instance of the low organisation of the professional conscience.

The uncertainty which existed as to the status of any medical practitioner was remarkably illustrated at the appointment of the original physicians and surgeons to the infirmary. Stonhouse, whose qualifications were impugned in common with those of Lyon, had little difficulty in demon-

strating his claim to be accepted. Lyon, however, could produce nothing which in these days would pass for a qualification. He had served Cunningham, a regular surgeon, for seven years as an apprentice, was a pupil of Cheselden for a year, was appointed to Joshua Simons for a year, and Rushworth had recognised him as a regular practitioner by placing himself under his care during his own illness, and committing his patients to his charge. Cheselden, Ranby, Shepton, and Bigg had also acknowledged him in consultation.

I must now devote a few moments to that veteran of our locality, Dr. Kerr. He stepped upon the scene in youth as surgeon-in-ordinary and colleague of his partner Litchfield. He soon reigned alone in surgery, till in 1793, with the title of superintending surgeon, he seized the sceptre of the empire of Medicine, and with the enlarged sphere of the new infirmary, of which he was the founder, he ruled as he would, supported only by his juniors, Harden and Loeck, till, amid the glories of age, he passed away, leaving the institution again with its unaltered constitution of two physicians and two surgeons.

As an operator he led the van, advancing the point of the amputating knife higher than any preceding surgeon into the region of the hip. Pioneers in surgery often mingle errors with their successes, and so it was with Kerr. Posterity has condemned the occasion of his interference, though it has justified its temerity. Surgeons do not now remove the limb at the hip joint amid suppuration and caries, involving the pelvis, though, with greater precaution, they follow his example in other cases. The record of this case and a four-page pamphlet on the prevention of hydrophobia by the use of mercury are his only contributions to medical literature. But in the open field of surgery he was always to the front, reserving for some special occasion, such as his birthday, any unusually brilliant performance he might be able so to postpone.

The adjoining building is the monument of his fame. To him was due the exposure of all the faults and incapacity of the old hospital in George Row, and his genius evolved all the principles of construction of the present infirmary with such success that to this day it would have been considered admirably adapted to modern requirements had not the necessity of addition revealed some minor drawbacks.

In the committee room his influence was paramount, but his method was not the resistless sway of a dictator, as his detractors insinuated. It was, as his letters show, by that *maîtrise en modo, fortiter in re*, which is more resistless still. Thus it came about that Kerr was the man whom the governors delighted to honour. His power did not, however, rest on words and phrases. Those were the days when apprenticeships were in vogue, and a man of eminence attracted many pupils, whose enormous fees, in this case, swelled the coffers, not only of the surgeon, but also of the infirmary. Three hundred guineas was paid by all resident pupils, and of his receipts from others Kerr commonly presented £50 to the institution.

Outside the infirmary his reputation was also established. The poet Cowper refers to him as "quite a gentleman, and a very sensible one." For public spirit he was also known in raising the body known as the Northamptonshire Fencibles, commanded by his son; and the volunteer cavalry of the county, of which he was himself the respected commandant. Before the close of his long career of sixty-one years, the governors entrusted the painting of the portrait hanging opposite to Thomas Phillips, R.A., and an excellent engraving was afterwards executed from it by Say.

One somewhat lesser light calls for a short notice before I close. You see around you, gentlemen, the records of the beneficence of past contributors to the infirmary, but some of you little guess that those extensive hoardings hide a museum the work almost entirely of one indefatigable worker. It was in consequence of the bequest to this hospital of the excellent anatomical and pathological models which the patience and skill of Mr. Holerton, once house surgeon, had made and collected, that this room in which we meet was erected. To the same genius the institution was indebted for an apparatus for reducing dislocation of the shoulder, and another for crushing stone—one of the earliest lithotrites ever invented. But these have been eclipsed by more perfect instruments and more scientific methods.

I will not weary you with further searchings among the tombs of those who have passed away. On us falls the burden which their shoulders once bore. We may easily point to the faults and foibles of those actors on Northampton's stage, but with their opportunities and disadvantages we might not have done half so well. If in our heavens the sun of knowledge has risen higher, and we no longer grope amid the veiled forms and shapes which met them in those twilight days, be it our aim to fight with at least as great zeal and determination as they to advance the progress of their race and allay the ills of our fellow men; not blurring our vision by prejudice nor weakening our powers by internecine strife.

MEDICAL POLITY, AND THE LAW AS IT DIRECTLY AFFECTS THE MEDICAL PROFESSION;

WITH SPECIAL REFERENCE TO THE POINTS WHICH SHOULD BE DEALT WITH IN A MEDICAL ACTS AMENDMENT BILL.¹

By A. BROWN RITCHIE, M.B., C.M. EDIN.

On January 12th last there was published in the *BRITISH MEDICAL JOURNAL* a Bill aiming at the suppression of practice by unqualified persons. That Bill has been condemned by the Lancashire and Cheshire Branch of the British Medical Association as being wholly inadequate, dealing as it does only with the assumption of titles or descriptions implying possession of a degree or licence, or even skill necessary for the practice of medicine, surgery, or midwifery, or any branch of these. The committee of this Branch, having had under its consideration, *inter alia*, that Bill, appointed a subcommittee to inquire into the question of what amendments were desirable, and to draw up a scheme which would serve as a basis or model, and indicate the lines on which a satisfactory Bill should run. In the paper which I have to read I am permitted to lay before you the result of the labours of that subcommittee. Our subject then is, "What are the points which it is desirable should be considered and dealt with in the framing of any Bill purporting to amend the Medical Acts?" In looking at the law as it now stands from this point of view, there are many unsatisfactory points of minor consideration. These, I think, it will be best to avoid. Let us take, then, the principal deficiencies.

Broadly speaking there are six lines on which reform may be advocated. These are:—I. The constitution of the General Medical Council. II. The powers of the General Medical Council. III. The powers of the corporations and universities. IV. Practice by unregistered persons. V. Medical advertisements (indecent, etc.). VI. Certification and registration of deaths.

I.—THE CONSTITUTION OF THE GENERAL MEDICAL COUNCIL.

At the present time 5 members of the Council are Crown nominees, 20 members represent the various corporations and universities, and are elected by cliques of professors or teachers and others, numbering together about 300, while 5 members directly represent the 20,000 registered medical practitioners. With the exception of Victoria University, which includes Liverpool, Manchester, and Leeds Medical Schools, from one of which a representative is sent every five years, each taking rotation, the representatives of the corporations are practically elected for life, and long service is apt to produce apathy, while in some cases the member does not represent the views and interests of the diplomates or graduates of his corporation. The dentists are controlled by the Medical Council: they pay a registration fee, and number about 5,000, but have no representative on the Council, nor has the Council power to appoint one. We propose to amend the present state of affairs by having representatives of corporations or universities elected by the licentiates, diplomates, or graduates of such; a limited term of office on the Council, say four or five years; a member representing the British Dental Association; or by an alternate scheme providing (1) district representation; (2) one Crown nominee;

(3) representation of universities and corporations in turn; (4) a member representing the registered dentists of the United Kingdom.

As the deficiencies in law regarding the powers of the General Medical Council, the powers of the Corporations and Universities, and the practice by unregistered persons, cannot be separated and put under the different headings, one often applying to all three, we will take them together and separate the subjects when we propose treatment for these deficiencies.

The chief points are: (1) Referring specially to the Council: In all matters of control, reform, regulations, recognition of diplomas, standard of proficiency, etc., the Council has no power to act, but can only make recommendations to the Privy Council, two members of which (a quorum) can control it, and through which everything must be done. There is no control over students. There is no control over unregistered persons. Registration is not compulsory for practice.—(Aberdeen Graduate.) A person may be disqualified without being disqualified.—(Sutherland.) Before disregistration the Council must conduct an inquiry which is costly, and could be done much more cheaply and quite as well by the licensing body.—(Partridge, Allbutt.) The Council does not receive the penalties recovered by them in London; they have to bear the costs of the prosecution in case of failure, but the penalty goes to the metropolitan police if the case is won. This is in cases of prosecution for false assumption of titles, etc. (2) Referring to Corporations and Council and unregistered practice. The regulations, standard of proficiency, course of study, and method of conducting examinations vary with the different Corporations. The only body which can prosecute unqualified practitioners is the Apothecaries' Society, and it can only prosecute for practice of medicine, not surgery or midwifery. The Universities (except Cambridge and Durham) cannot withdraw a degree.—(Sutherland.) Some of the Corporations can withdraw, but not restore, a diploma. An infinite variety of titles or descriptions, implying skill necessary to treat disease or injury, can be used by unqualified persons without infringing the present law. An unqualified person may practice without assuming any title or description. A person falsely assuming a title, or pretending to be a physician, etc., must first be warned, and can only be prosecuted if he persist in so doing. An institution wholly supported by voluntary contributions may employ an unqualified medical officer or surgeon. A registered practitioner is liable to be sued for damages for neglect, want of skill, or injury, while an unqualified person is not, though both are supposed to be, equally liable by law. (A registered or qualified practitioner is supposed to have competent skill for treatment. If there is no qualification you cannot assume skill, and if the case requires skill for treatment, and no malice is proved against the unqualified man, there is no case for damages.) The public have to pay the costs of inquiries directly caused by practice of unqualified persons.—(Harpurhey Chemist.) Dispensaries may be carried on anonymously when it is difficult to get at the responsible person or to know whether he is qualified or not, etc. Any person may use the name of a duly qualified practitioner with reference to an appliance or proprietary medicine, and the practitioner can get no injunction or restraint, nor can he recover damages for injury to status caused by this practice.—(Williams, Henry Scott, Dr. Fox, etc.)

II.—THE POWERS OF THE GENERAL MEDICAL COUNCIL.

Taking as our model the profession of law, we find that the Council of the Inns of Court is the supreme authority. There is no Privy Council interference—the Council acts independently. The various Inns send representatives to the Council, which controls them as regards examinations and suggests regulations for their adoption. The Inns govern themselves, but as regards affairs common to all they are subject to the Council. There is a uniform examination, but each Inn calls its own students—that is, admits to the bar. We propose to extend the powers of our Council over (1) registered students, (2) registered medical practitioners, (3) foreign and colonial practitioners practising in the United Kingdom, (4) medical Corporations and Universities, (5) unqualified practitioners and their employers.

¹Read before the Council of the Lancashire and Cheshire Branch of the British Medical Association.

These powers would include granting a representative to any corporation (for example, Dentists' Association). Enacting laws and regulations for the corporations (aiming at uniformity). Making regulations as to course of study, method of examination, etc. Conducting or supervising examinations of corporations. Demanding inquiry by corporations as to conduct of their graduates or licentiates. Discipline over students and practitioners for unbecoming conduct, etc. (by means of bond and declaration signed previous to registration). Compelling registration simultaneously with qualification and making these concurrent. Precedent—Dentists Act, 1878, Clauses xiii and xiv.) Issuance and restoration to Register. Cancelling of licence or degree and restoration of same. Suspension of licence or degree or from Register. Raising or altering fees for registration (annual or compounding). Conducting inquiry by means of judicial committee. Prosecution of unqualified persons practising in medicine, surgery, or midwifery, or any branch thereof. Prosecution of employers of such practitioners having unqualified deputy). Prosecution of persons allowing employment of such (managers or companies allowing doctors to employ an unqualified deputy to do the work). Right to penalties recovered in London. It is also desirable that all premises used for or in the practice of medicine, surgery, or midwifery should bear the name of the person so practising, exposed to public view. And that no institution, whether wholly supported by voluntary contributions or not, shall be allowed to employ an unqualified person as medical officer, surgeon, etc.

III.—THE POWERS OF THE CORPORATIONS AND UNIVERSITIES.

These would require powers of discipline over graduates or diplomates (by means of bond and declaration signed previous to registration, and by granting diplomas to be held conditional to observance of by-laws and regulations). Cancelling, withdrawing, suspending, and restoring a diploma or degree. Raising or altering fees for examination or registration.

IV.—PRACTICE BY UNREGISTERED PERSONS.

There are many ways of checking irregular practice. As precedents to our proposals we have, with regard to unqualified practitioners, the Solicitors Act, 1843, Sec. ii and viii; the Apothecaries Act, 1875, Sec. xiv and xx (as to assistant, Sec. xvii); with regard to assumption of titles or descriptions, the Dentists Act, 1878, Clause iii; the Veterinary Act, 1881, Clause xvii, Sec. i. We suggest therefore a penalty for the practice, direct or indirect, of medicine, surgery, or midwifery, or any branch of either of them, for or in expectation of gain or profit.—(Mr. Whitehead's resolution.) A penalty for assumption of titles or descriptions implying qualification or even skill necessary for the practice of medicine, surgery, or midwifery, or any branch of either of them, or administration of medical treatment. (JOURNAL BILL, January 1904, Dentists and Veterinary Acts.) We also propose a penalty for the employment of an unqualified deputy in cases of public appointments, mines, works, etc., which are contracted for at a low fee and worked by unqualified assistants). A penalty for allowing employment of unqualified deputy (selecting managers or companies or owners of mines, etc.). Right of action for damages (tort), if cause for such, when a person is attended by an unqualified practitioner, any contract to the contrary notwithstanding, that is, without the unqualified person having the power to bind a patient not to prosecute him. Right of action by representatives, if cause for such, when a person dies, having been treated by an unqualified practitioner, any contract to the contrary notwithstanding. Criminal proceedings for injury or death caused by unqualified practitioner. Right to public to recover fees paid to unqualified practitioners. Fine of costs in cases of loss or costs caused by attendance of unqualified practitioner. And that any person using the name of a duly qualified practitioner with regard to any appliance or proprietary medicine shall on demand show evidence of his having received authority to do so, and if he cannot he shall be liable to an action for damages by any duly qualified practitioner bearing the same surname as that used.

V.—MEDICAL ADVERTISEMENTS.

The Indecent Advertisement Act applies only to London

and such cities as have adopted it—for example, Liverpool. It only makes the posting up to public view or the delivery of pamphlets, pictures, or advertisements of that character penal, and does not apply to advertisements in the newspapers, nor, it seems, to those on sandwich boards or sent through the post. This requires making the London Act refer also to newspapers and sandwich boards, etc.; extending it to the United Kingdom; including within its scope advertisements suggesting the procurement of abortion—"removal of obstinate irregularity," etc.

VI.—CERTIFICATION AND REGISTRATION OF DEATHS.

At present the registrar, an unqualified person, is the judge as to whether there are suspicious circumstances about a death or not. Unregistered persons may notify a death, and their notification is accepted.—(Herbalist.) Certification of the fact of death and identification of the body are not necessary. Fraud by personation of living by dead, obtaining certificate by false information, or forging certificate is easy. The medical practitioner gets no fee for the certificate of death, while the registrar is paid for copies of it. The practitioner is not bound to certify that he attended deceased in the last illness. There is no definition of "attendance during last illness," nor rule as to when a certificate must be given and when not. A very large proportion of stillbirths are uncertified, or certified by unqualified persons (midwives and others); 45 per cent. in Manchester are so certified. Stillborn children need not be buried in a public burial ground, and if not, neither the birth, death, nor burial need be registered.

Following the recommendations of the Special Commission appointed to inquire into this subject—at least in their main lines—we propose: That all uncertified deaths be compulsorily reported to the coroner; that no certificate issued by an unqualified person be accepted; that the fact of death be certified and the body identified; that certificates of death and all copies thereof be got directly from the practitioner; that there be a fee for each certificate or copy; that grounds should be defined for refusing certificates; that "attendance during last illness" should be defined; that stillbirths should be registered and certified the same as ordinary deaths.

Gentlemen, we, as registered medical practitioners, have a recognised legal status. That the benefits accruing from this are so insignificant is, in my opinion, largely due to the apathy and want of cohesion in the profession. The proposals which I have submitted to you are already considered Utopian by some, and no doubt will be by others, as are most schemes of a comprehensive nature when first put forward. These proposals are not original; they have nearly all been advocated by others before, but are now brought together as a whole. We must remember that in advocating provisions which shall be of advantage to our profession, if we are to hope for some measure of success, they must be blended with others which are directly of advantage to the public; this is most clearly shown in the provisions for suppression of practice by unregistered persons. To my mind there is nothing either impracticable or unreasonable in any of our proposals, and Dr. Gledhill, barrister-at-law, to whom I am indebted for the information contained in this paper, has undertaken to show the necessity or advisability of any one of them.

A FURTHER ANALYSIS OF THE WATER OF THE ZEMZEM WELL IN MECCA.

BY

E. H. HANKIN, AND DR. RAPUJI P. GADIALLY,

M.A.,
Fellow of St. John's College, Cambridge;
Fellow of the Chemical, Bacteriological and
Toxicological Societies of the North-West
Provinces and Oudh, and to the
Central Provinces.

M.B.B.S.,
Assistant to the Chemical
Examiners.

(From the Government Laboratory, Agra, India.)

We owe to the kindness of Mr. Ernest Hart the opportunity of making a fuller examination of Zemzem water than that reported by one of us in the BRITISH MEDICAL JOURNAL of June 30th, 1894, p. 1412.

The specimen of water in question was brought from Mecca in the year 1894 by Haji Abdush Shukur. The quantity was about 500 cubic centimetres. The results of analysis are shown in the following table, together with the analyses of water from three other sources for comparison:

Source of Water.	Total Solids, Grains per Gallon.	Chlorine, Grains per Gallon.	Total Hardness, Grains per Gallon.	Fixed Hardness, Grains per Gallon.	S as Nitrogen, Parts per Million.	S as Nitrogen, Parts per Million.	Free Ammonia, Parts per Million.	Total Alkalinity, Parts per Million.	Sediment.
Zemzem Water, from Surgeon-Major Hanlin	299.0	11.24	—	—	—	—	0.01045	—	Scanty sediment.
Zemzem Water, from Mr Ernest Hart	350.0	77.90	—	—	0.0004	0.0004	0.01024	—	Very slight.
Water from Jacob Koti Agra	31.0	1.40	4.0	2.8	—	—	0.00007	—	None.
Agra Municipal Water	12.0	2.25	5.0	2.8	—	—	0.00004	—	Note.

It is almost superfluous to point out that each one of the results contained in the above table indicate that the water from the Zemzem well must be subject to a large amount of contamination.

The water was also subjected to a qualitative bacteriological examination. A "vibrio," or "comma bacillus," and a microbe resembling the *E. coli communis* in every respect, except that it did not give the indol reaction, were isolated. The "vibrio" exhibited the ordinary characters of the group when cultivated on different media. It differed from a typical cholera microbe (if the term typical may be ascribed to so variable a microbe as that of cholera) in that it was harmless to guinea-pigs when injected into the peritoneum, and it only gave the indol reaction faintly in a ten-day-old culture and not at all in fresh cultures.

In several cholera epidemics in different parts of these provinces we have found that the cholera microbe was almost universally present in well water at the time of the outbreak, that a short time after the outbreak it was still present, but showing various cultural characters that may be taken as signs of degeneration, and that at a later period (two or three months) it had completely vanished except in a few exceptional instances. Consequently it appears that the finding of a vibrio in water is a sign that it has been exposed to human contamination, and that it may have been concerned in the production of cholera. That the vibrio we met with in the Mecca water had such significance we could not at once conclude, for the water appears to have been brought from Mecca in a vessel that was not hermetically sealed, and had been decanted into a bottle before being sent to this laboratory. We owe our thanks to Surgeon-Major Roberts, of Aligarh, who sent us a further specimen of Zemzem water which reached us within two months of its collection. This water was contained in a hermetically sealed tin vessel known as a "dibia." There was therefore in this case no chance of further contamination after the water left Mecca. In this water we discovered a vibrio which appeared to be a little less attenuated than the other, for its three-day-old cultures gave the indol reaction, and it killed a guinea-pig in thirty hours.

We have applied to the Zemzem water what we believe to be a new method of estimating its fitness for drinking purposes. We have tested its capacity of acting as a culture medium for the cholera microbe. It is, we think, obvious that the presence of not living organic matter in water is objectionable not only because it may be evidence of sewage contamination, but also because it may act as food for microbes. It would seem probable that in the latter respect a direct experiment would give more reliable results than a chemical analysis. The adjoining chart contains the result of our experiment in a graphic form. Three specimens of water were used in this experiment; one, as already mentioned, was the Zemzem water; the second was water from a well in Agra known as Jacob's Koti; the third was the Agra municipal water. Ten cubic centimetres of each kind

Numbers of Hours after the Inoculation of the Water Samples.

of water were put into test tubes and sterilised in an autoclave. They were then inoculated with cholera microbes that had been cultivated for some days previously in very dilute peptone solutions. Immediately after the addition a test was made to see how many cholera microbes were present in a cubic centimetre of each of the specimens of water. At intervals other similar tests were carried out. The results are shown in the chart. It will be seen that (1) in Agra municipal water the cholera microbe nearly or completely dies out within two days, (2) that in Zemzem water on the other hand the cholera microbe reproduces vigorously. At first a slight diminution in numbers took place, but after this the microbe reproduced with facility. (3) In the Jacob's Koli water a similar reproduction of the microbe occurred.

If the above experiment can be taken as representing a natural occurrence, it may be expected that the cholera microbe would produce far more serious effects if it got into the Zemzem well than if it got into Agra pipe water. The latter water is derived from the Jumna, and is subjected to Anderson's purifying process before it passes into the pipes. Other experiments have shown us that probably the bactericidal action of Agra pipe water is also possessed to some extent by the original Jumna water, from which it is prepared. Control cultures were made, and proved that we had to deal with a pure culture of the cholera microbe in the above experiment.

A noteworthy fact may be seen from an examination of the appended curve, namely, that no definite relation exists between the chemical composition of the different specimens of water and their power of nourishing the cholera microbe. On comparing the data for the Zemzem water with those for the Jacob's Koli water, it is seen that the water that is better chemically is the better food medium for the cholera microbe. Further, the comparatively slight difference chemically between the Jacob's Koli water and the Agra pipe water gives no indication of the difference in their powers of nourishing the cholera microbe. It is conceivable that the application of this test on a larger scale might lead to an explanation of certain cases of "local immunity" against cholera.

A PROTEST AGAINST OVER-TREATMENT IN ECZEMA.

By MALCOLM MORRIS, F.R.C.S. Ed.,

Surgeon to the Skin Department, St. Mary's Hospital.

There is no general formula for the treatment of eczema, and, to use a famous phrase, no one—not even the youngest among us—is infallible in his methods of dealing with it. Here, however, as in the case of other diseases, he will be most successful who tries to see things as they really are, and not in the light of any preconceived theory. Of the clinical facts of eczema we probably know nearly all that is to be known; of the laws which govern the evolution of the process we know something; of the pathological forces which set it in motion we know little or nothing. But if little is known a great deal has been imagined, and the subject has been enveloped in an atmosphere of hypothesis which in practice too often darkens counsel. The notion is still somewhat widely prevalent that eczema is the expression of a definite constitutional "diathesis," or in the language of the old pathology (from which the professional mind has not even yet altogether shaken itself free) the outward and visible sign of an inward "peccant humour" of some kind. This superstition, for it is nothing else—leads to errors in the treatment of the disease in two opposite directions—on the one hand of doing too little; on the other, of doing too much. Some, believing that the skin lesions act as "lesions" whereby the supposed mischievous principle is withdrawn from the system, leave them untreated in the fear that the healing of them might cause "morbid determinations" to internal organs—a fear for which, according to my experience, there is simply no foundation. Others direct all their therapeutic efforts to forcing on what they call a "crisis," their plan of campaign apparently being to drive the enemy into the open country where he can (in theory) be crushed without difficulty. It is, naturally enough, at hydropathic institutions

that this method is most in favour, for there "critical eruptions" are among the usual incidents of the treatment, and therefore easily come to be looked upon as being an essential element in the cure. There is something seductive in the notion of bringing the disease to the surface, and there dealing with it in a summary fashion, but unfortunately the plan does not answer in practice. It is much easier to fan the flame of eczema than to subdue it. The "critical eruption" is very apt to forget that it is merely a strategical manoeuvre, and to behave exactly as if it were a natural exacerbation of the disease; like a foreign power called in as an ally it sometimes remains as a conqueror, more oppressive and more difficult to get rid of than the original enemy.

I have seen so many cases of eczema made worse by misdirected therapeutic energy that I think it my duty, for the credit of the profession as well as in the interests of patients, to say a few words of warning on the subject. The importance of avoiding this error has quite recently been impressed on my mind by the following case which I relate as a typical example of the evils of over-treatment in eczema. I give it as far as possible in the words of the patient, who is of intelligence and position:

On January 9th I consulted a doctor at the request of my friends, and told him of my complaint, which up to that time had been pronounced as gout coming out. The doctor told me I was suffering from eczema in an acute form, and put me on a diet and treatment. This, however, did not seem to be the correct treatment, for I grew rapidly worse and took to my bed. On March 9th I went on leave to my father's house, and there saw the family doctor, who at once recommended a course of hydropathic treatment. I went to a well known hydropathic establishment on March 20th, being only then at all travelling. I was on arrival put to baths and massage in all its forms. At 7 A.M. I had a glass of hot water, followed by a Russian bath at 100°. At 10 A.M. I saw the doctor, and then had a sitz bath of oatmeal and boracic acid at 70° F. At 3 P.M. I had a cool pack to make me perspire freely, and then was at once given an oil enema. At 8 P.M. I had a series of bandages put on: (1) To the spine, between shoulders (bread and chills); (2) to the abdomen, to produce a crisis (bread); (3) to the anus, the part affected, to soothe (bread and boracic). If the irritation became intense at night I was to apply a solution of cocaine and water; if this was useless to use a solution of coal tar and olive oil. For insertion into the anus a suppository of cocaine, cocoa butter, and oil of olives. On these remedies I continued, with restricted diet—only fish and chicken, oat flour, hot water and dry toast, mutton once a day (meals three only)—till May 4th. My eczema when I went to the hydropathic institution consisted of an intertrigo at the anus and round the testicles slightly. When I left on May 4th I had a broad band on the abdomen, highly irritable and suppurating readily; the patch on the testicles had spread down along each leg; the patch round the anus had spread from the hips to a plentiful covering of each buttock. I could not sit or walk, and was forced to sleep in a standing posture, leaning my shoulders against the walls or balancing my legs and shoulders on to armchairs, with a support for the hollow in the back.

There is nothing remarkable about the case here recorded, but it serves to point a moral. A localised eczema had been aggravated by over-treatment till it was on the way to become general; the bread poultice intensified the inflammatory process and the bandages acted as vehicles for the conveyance of inoculable material to the parts to which they were applied. The dietetic restrictions helped to lower the patient's strength without having any beneficial effect on the disease. The plan of treatment, in fact, was founded on an erroneous notion as to the nature of the disease. It cannot be too strongly insisted upon that though some constitutional disorder, such as gout or diabetes, is sometimes associated with eczema and may indirectly react on the skin affection by its effect on the patient's health, eczema in itself is essentially a local catarrh, and as such should be treated by local remedies. Even in the use of these the practitioner should be guided by the spirit of Tulleghand's maxim: *Sedare, Minuere, post temp. deinde*.

Too much zeal in the use of strong remedies which cause irritation is more disastrous than the do-nothing policy of those who look upon eczema as a usual dermal affluence. My own method of treating the disease has been fully described elsewhere; it need only be stated here that I trust mainly to local applications of antiparasitic substances, finding my way with the greatest caution so as to destroy the agents which are causing the eczema without setting up additional inflammation. Constitutional treatment is employed only when there is definite evidence that it is required.

The Gaskell Medal and Prize in Mental and Nervous Diseases has been awarded, after examination at the Royal Bethlem Hospital, to George W. F. Macnaghton, M.B., O.M. Ed'n.

ACQUIRED SUBLUXATION OF THE KNEE-JOINT IN YOUNG CHILDREN.

By H. BETHAM ROBINSON, M.S.LOND., F.R.C.S. ENG.,
Assistant Surgeon to, and Demonstrator of Anatomy at, St. Thomas's
Hospital; Assistant Surgeon to the East London Hospital for
Children, Shadwell.

During the past two years in my out-patient room at the Shadwell Children's Hospital I have had three cases which presented the lesions denoted under the above title. As the condition is evidently a rare one, and I am not aware of any previous reference to such a lesion, I have thought them worthy of being embodied in a short paper. One of the cases, S. C., I exhibited at the Clinical Society in April, 1894, when the diagnosis was confirmed by many present, and short notes of this case appear in vol. xxvii of the *Transactions*.

Before detailing the cases I would lay stress upon the following facts as being common to all, and as giving an indication as to the causes at work to bring about this condition. All three cases were in young female children close on twelve months old, who had all been previously healthy and just getting on to their feet. All suddenly, from some altered condition of health, perhaps associated with teething trouble, got flaccidity of the muscles of the lower extremities and probably laxity of ligaments, and, with the advent of this loss of support, the altered movements in the knee-joints were noticed. In none of the cases was there any evidence of rickets, nor was there any reason to consider the wasting associated with any infantile paralysis.

As will be noticed, from the accounts of the cases, a favourable prognosis may be given. With simple internal remedies to restore the general health, and rubbing the leg muscles to increase their bulk and tone, the looseness of the joints soon disappears, leaving apparently no evidence behind.

CASE I.—E. M., aged 9 months, came to my out-patient room on May 12th, 1893. She had always been healthy, and was the youngest of eleven children. The birth was normal. For the past few days the child had been out of sorts and peevish, apparently in relation with dentition. The mother noticed that she had developed some looseness of knee-joints and general flabbiness of muscles, particularly of the lower extremities. On examining the knees, there appeared no deformity. The joint surfaces and patella were normal, and the relation of the tibia and fibula on either side to each other was quite natural. The range of movement in the knee-joint in the antero-posterior direction was not altered, but lateral displacement could be easily effected. On watching the knees, the child is noticed to shoot the tibia and fibula outwards laterally, at the same time rotating the bones outwards, so that the inner tuberosity of the tibia is directed almost forwards, while it occupies the intercondylar notch. The bones are actively returned to the normal position with a loud snap. The child was given *vinum ferri*, and the knees and muscles were ordered to be rubbed by the mother with *lin. saponis*. On June 27th, the condition was very much improved. The muscles had recovered some of their tone, and the displacement could not so readily be brought about. The child also was beginning to get down on its feet again. The improvement was maintained, and the child soon got all right. The child was brought up to me for inspection on April 20th, 1894, when her knees were absolutely right, except perhaps for a slight excess of lateral movement. The muscles were bulky and firm, and she could stand and walk well.

CASE II.—S. C., 1 year old, came under my care on February 20th, 1894. She had bronchitis at Christmas. The child before that had been in good health and very strong. Since that time she had not been able to stand down on her feet, and her leg muscles were not as firm as before. There was no evidence of rickets. She was the first child. With the onset of the inability to stand, the mother noticed that the bones of the knee were displaced, returning to their normal position with a loud snap. On watching the child the tibia and fibula on each side were seen to be displaced outwards and forwards, so that the inner tuberosity of the tibia came into the intercondylar notch and looked directly forwards. On manipulation there was some lateral movement but not

as much as in the other two cases. The legs were ordered to be well rubbed with *lin. saponis*, and *iron* and *strychnine* given internally. Up to March 6th the child very much improved but she then developed measles. When next seen towards the end of the month the legs muscles were very flabby, and the looseness of the knee-joints was much more marked. She was shown at the Clinical Society on April 27th, when the condition was easily demonstrated. From this time, as she improved in health, the displacement became less and less noticeable, and when last seen, towards the end of the year, her muscles were firm and strong; there was no displacement to be detected, and she could stand and walk fairly well.

CASE III.—E. D., aged 9 months, first came under my care, October 2nd, 1894. She had always been a very healthy child, and could just stand on her feet but not walk. Three weeks before the first visit she had a fall, and it was after this that anything abnormal was first detected in the legs. When the child moved her knees it was noticed that they now creaked. The only other features worth noting are that the child appeared "out of sorts" after the fall, and her muscles seemed weak so that she could not now stand. The legs, especially the right one, could be easily rotated at the knee joints, so that the inner tuberosity of the tibia came into the notch. This same position could be effected by crossing one leg over the other. Voluntarily the normal position was reassumed with a loud snap. There was also in this case some freedom of movement in ankle joints. A week later the muscles were more flabby, and in consequence the looseness of the joints was more marked. Under treatment the muscles rapidly regained their proper tension, and with this the abnormal movement of the joint surfaces was less and less able to be demonstrated.

REPORTS

ON

MEDICAL & SURGICAL PRACTICE IN THE HOSPITALS
AND ASYLUMS OF GREAT BRITAIN, IRELAND,
AND THE COLONIES.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND
STREET.

A CASE OF SPINA BIFIDA CURED BY EXCISION.

(Under the care of Mr. MORGAN.)

[By GERALD R. BALDWIN, F.R.C.S., Surgical Registrar.]

W. B., a boy, aged 2 months, was admitted into the Children's Hospital on June 14th. From birth he had had a tumour in the back. Examination showed the presence of a large and very tense spina bifida in the lower lumbar region of the spine. In size it was nearly as large as a coconut. The skin round the base was normal, but that over the more prominent part of the tumour was red, scar-like, and translucent. There was a free impulse between the tumour and the anterior fontanelle, which was widely open. No umbilication was noticed. There was free movement of the lower limbs, and perfect control over the sphincters. No other deformity was present.

On June 14th Mr. Morgan tapped the tumour with a hydrocele trocar and cannula, withdrawing 6 ounces of cerebro-spinal fluid. After the contents had been withdrawn a large gap was perceptible, corresponding to two or more of the lumbar spines and laminae, which were deficient. Next day the tumour was as large and tense as before tapping, but no bad symptoms had followed. Therefore, as no signs pointed to the presence of nerve tissue in the sac wall, it was decided to excise the tumour. Another and stronger reason for adopting this method of treatment was the almost uniformly unsuccessful result which Mr. Morgan has experienced with other methods of treatment. The injection of Morton's fluid and simple tapping have both been tried on several occasions without success. In some cases death has rapidly followed these methods, and in others life has been preserved for only a short time after treatment. Accordingly on the 22nd, after a preliminary tapping, the tumour was excised. The sac wall was formed of skin and

and membranes without any nerve tissue, but the sac was situated with the vertebral canal through an opening in the skin, as a three-penny piece. The presence of this communication was suspected before operation on account of the rapid swelling up of the tumour after the first tapping. Both the wall and skin were united with silkworm gut, and the wound was powdered with iodoform, over which flexible collodion was painted. Pressure was applied to the wound by means of elastic wool and an ordinary medium-sized bandage.

On the morning of the 24th the child's temperature was 101°, and on that evening and the following morning it had risen to 102°, but fell to normal next morning. There was also temporary paralysis of the bladder requiring the employment of a catheter on the 23rd, 24th, and 25th, but since then the urine has been passed naturally. These were the only serious symptoms following the operation, although several stitches gave way, and for a time a small quantity of cerebro-spinal fluid escaped. On several occasions the child vomited, but this was stopped by lessening the quantity of milk.

On July 13th the wound had healed completely, and at the present time the only thing to be noticed is a slight protrusion of the scar when the child cries. This is natural, considering the number of spinous processes which are deficient.

REMARKS.—Of course excision is practicable in only a small number of cases of spina bifida. The favourable symptoms in this case were the perfect control over the limbs and sphincters, the absence of umbilication, and the translucency of the growth, which pointed to its being a case of simple meningocele. It was only as a desperate remedy for an otherwise certainly fatal disease that the treatment was adopted, and a very successful result appears to hold out hopes of curing other favourable cases in a similar manner. The case will be exhibited with other patients by Mr. Morgan at the meeting of the Section of Diseases of Children of the British Medical Association on Thursday, August 1st.

REVIEWS.

ARMSTRONG'S LUNACY. Fourth Edition. By S. G. LUSHINGTON, M.A., B.C.L. London: Shaw and Sons. 1895. (Demy 8vo, pp. 1165. 42s.)

THIS edition comprises The Lunacy Acts 1890 and 1891, the Lancashire County (Lunatic Asylums and other Powers) Act, 1891, and all the statutory rules, orders, and forms in force thereunder, also the statutes relating to criminal lunatics, the Lunacy (Vacating of Seats) Act, 1896; and the Idiots Act, 1892.

The book forms a partly volume of nearly 1,200 pages. The table of contents and table of cases occupies 51 pages; 207 are devoted to an introductory part, and 805 pages are taken up with the Acts, and commentaries, and explanations on their sections, as well as with a very full general index.

The "Introduction" is a valuable part of the work, giving in easy form a summary of the chief provisions of the various Acts, together with due references to the sections of the Acts which bear upon the particular points which are being dealt with. Following each of the numerous sections and subsections of these long and intricate Acts, and in smaller type, so as not to be confused with the wording of the Acts themselves, there are references to the pages at which the legal definitions of the various terms used may be found, and explanations as to the bearing of some other paragraph, or case, or decision on the particular section, so that the reader consulting the work is spared a large amount of unnecessary research, and has his attention directed immediately to all the essential provisions without being compelled to study an index with anxious care, and to turn to the text of every reference on the subject found under the heading of the particular points on which the work is being consulted.

To the legal profession, also, the book is valuable, and for the fact, among other reasons, that it distinctly states wherefrom each section is taken, and, indeed, a little summary history is sometimes given of the various preceding enactments, amendments, and alterations as to the provisions of the section under scrutiny.

The explanations given are plain. Selecting at random a short example, we notice under Section 36, subs. (1); and following the wording of the subsection; that there are instructions where to find the definition of words used in the subsection, statements of what the subsection is a re-enactment, and that it relates only to summary reception orders; references to the provisions for suspending such orders, and as to temporary removal to workhouse, being also added.

NOTES ON BOOKS.

Infant Feeding by Artificial Means. By S. H. SADLER. (London: The Scientific Press, Ltd. 1895. Cr. 8vo, pp. 234. 5s.)—The importance of the subject discussed in this book will not be disputed, and Mrs. Sadler has brought together much reliable information upon the various divisions of the subject. After discussing briefly the general principles which must be understood in all cases, she deals in succession with cow's milk, condensed milk, and with the milk of goats, mares, and asses. Many useful receipts and alternative methods are given for preparing cow's milk, and the remarks on the use of condensed milk are sound. Special attention is directed to the danger of putting the infant on a starvation diet by using the condensed milk too much diluted—a very common error. The book is rather diffuse, but this is perhaps a fault in the right direction. It is copiously illustrated, and many of the drawings will have all the charm of novelty in this country, where the direct suckling of infants by the goat and ass is not resorted to, and where, indeed, the process is unknown to the general public except through the pages of Daudet's *Nabob*, where the results are not represented in a very favourable light. This was, perhaps, owing to the exigencies of the plot.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND
THE ALLIED SCIENCES

IMPROVED ARTERY FORCEPS.

DR. E. MANSEL SYMPSON (Surgeon to the Lincoln County Hospital) has sought, in the artery forceps illustrated in the accompanying woodcut, to obviate a defect which he finds in nearly all of these instruments. In tying an artery it is desirable that the assistant's fingers should be well out of the way, but in the ordinary pattern, roughened for only half the length of the shaft, it is difficult to get a firm grip unless the finger and thumb are placed low down on the roughened portion, when there is the further objection that there is a considerable risk of loosening the grip. In the forceps designed by Dr. Sympton and made by Messrs. Arnold and Son the sides of the forceps are roughened for nearly three quarters of their length. The improvement also makes the forceps more convenient for use as tentacula for dealing with small tumours, since the longer the pull the easier.

MEDICAL MAGISTRATE.—Mr. Basil Hemcraft, of Southampton, has been placed upon the Commission of the Peace for the borough of Southampton by the late Lord Chancellor.—Mr. R. D. Evans, surgeon, has received an intimation that the Lord Chancellor (Herschell) has placed his name on the Commission of the Peace for Merionethshire.

BRITISH MEDICAL ASSOCIATION.

[The following Reports of the Council and of the Committees will be presented at the Annual Meeting to be held in London on July 30th and 31st and August 1st and 2nd, and are published in accordance with the regulations for the conduct of Annual Meetings, which require that all Reports of the Committees of the Association shall be printed in the JOURNAL before the Annual Meeting.]

REPORT OF COUNCIL OF BRITISH MEDICAL ASSOCIATION FOR 1895.

On the occasion of the annual meeting of 1895, your Council have the pleasure of meeting you, after the lapse of twenty-three years, in the metropolis of the British Empire, and, in accordance with By-law 19, of presenting to you the Sixty-third Annual Report.

Since the last meeting held in London in 1873 the Association has been entertained in many of the principal cities and towns in the United Kingdom, so that it has now become the privilege of the metropolis to entertain the members and to show again the hospitality for which it is so justly distinguished. From the great increase in the number of members throughout the British Empire the present meeting is expected to be both large and representative. The Council trust that the accommodation provided for the general meetings in Exeter Hall and the sectional meetings in King's College and the Conjoint Examination Hall (the two last-named institutions have been most kindly lent by the authorities), will prove adequate for the occasion. Every possible exertion has been made to meet the convenience and comfort of the members and guests attending the meeting.

During the year 1894 the revenue was £36 571, while the expenditure, inclusive of losses on subscriptions from deaths and resignations, was £32 043, leaving a surplus of £4 528; of this £3 528 has been invested in Bristol Three-and-a-Half Per Cent Corporation Stock. The estimated value of assets over liabilities is £99 454, and the savings of the Association amount to £45 359. It is expected that a large part of this sum will be shortly required, either for a renewal of the lease of the premises at present occupied by the Association or in acquiring land and building new premises. The Premises and Library Committee have for some time past been employed in the consideration of this important matter.

The investments were valued at the end of the year and were found to have increased in value since the original purchase by £6 391, showing the care with which they have been made.

The number of members reported on the books last year was 15,090. During the year 1,223 new members have been elected, 193 have died, and 451 have resigned, leaving on the books 15,060.

The JOURNAL has, in addition to the usual literary and scientific matter, occupied itself usefully with the thorough investigation of the system of barrack schools as against boarding-out; it is an important question in which medical opinion can most usefully influence the public and the Government, and a series of articles published has formed the basis of an important departmental Commission which is likely to take a new departure. The services thus rendered have been extensively and widely recognised. A systematic investigation has been made of a great number of provincial workhouse infirmaries with the view to extending throughout the country benefits of that improved medical and nursing organisation which has done so much to raise the character of the treatment of the sick poor in the metropolis under Gathorne Hardy's Act. These reports, 51 in number, have produced already a most beneficent and widespread result, not only in the particular places which have been the subject of investigation and report, but also collaterally by their influence on the standards of the Local Government Board, and the methods adopted by its inspectors. A circular has been issued by the Local Government Board in accordance with the general views expressed in the reports of the BRITISH MEDICAL JOURNAL. Every one of these reports has, it is understood, been brought before the official inspectors, who

have been desired to comment upon them, and to suggest such proceedings as may be necessary. Cordial acknowledgments are due to Mr. Shaw Lefevre and Sir Walter Foster for their sympathetic and effective action in relation to these reports, of which the good effects are far reaching and likely to be continuous. The reports of Dr. Woodhead and Dr. Cartwright Wood on filters have also disclosed most important results as to the necessity for the adoption of a very much more rigid standard in respect to filters. These reports are likely to have important results in this country and in India, where it has been shown that the inefficiency of potable water filters is the widespread cause of the cholera and typhoid epidemics. It is anticipated that some steps will be taken to secure standards of filters similar to those adopted in respect to thermometers and chronometers at Kew. The widespread and favourable reception of the BRITISH MEDICAL JOURNAL beyond the limits of the United Kingdom has once more been evidenced by the public demonstrations and receptions with which the Editor has been received throughout India during his winter visit there.

The Library is now becoming well established, and forms in itself a useful branch of the work of the Association. Three lists of presentations have been published during the year, and a fourth is well in hand. From the items contained in these lists it will be seen that new editions and new works form no inconsiderable part of the additions of the past year, and for these the Committee desire to express their thanks to numerous members of the Association for their contributions generally, and to the Honorary Librarian in particular, from whom such specially valuable works have been received during this past year. The number of attendances made is steadily increasing, there having been 4,500 during the past twelve months, which shows an increase of 14 per cent. over those of the previous year. In letters received and by remarks frequently made, members express great satisfaction at being able to consult some of the latest and most valuable works without the delay attending a visit to a larger library. The library contains considerably over 7,000 volumes as well as a number of pamphlets and a complete series for several years past (with index) of the Paris *Theses*, which it is believed are not to be consulted elsewhere in London. During the year 470 odd and duplicate volumes have been presented by request to other medical libraries, and further applications are awaiting consideration. Special thanks are also due to a great many medical officers of health who, in responding to our request for their reports, have done so far more generously than in former years.

The Council have much satisfaction in announcing that it has been decided by the New Zealand Medical Association to join the British Medical Association as one of the colonial Branches.

An important Branch has been recognised for Singapore and Malaya.

Both the Council and the Committees of Council have had much anxious work during the past year. In October last the question of medical aid associations was referred to the Council from the annual meeting, and was considered together with a resolution passed at the East Sussex District of the South Eastern Branch asking for an inquiry into the grievances, wants, and requirements of the general practitioners as they are found to exist in the Branches of the Association.

A Committee of the Council was appointed to consider the various questions involved. An interim report has been drawn up by the Committee, which will be laid before you separately; the Committee proposes to continue its work, the various complicated questions laid before it being of great difficulty, and requiring much consideration.

In January last a deputation from the Cork and South of Ireland Branch waited upon the Council of the Association to ask for their advice and support in the movement then going on against the extremely inadequate rate of payment of professional attendance by the clubs and benefit societies at Cork. After hearing the deputation, your Council passed the following resolutions:—

Resolved: That the Council of the British Medical Association receive most cordially the deputation from the South of Ireland Branch, and much regret to hear of the unfortunate contention which has occurred within the area. The Council

strongly condemn the admission of improper persons as members of medical aid societies. They deeply sympathise with those medical men who have been compelled to resign their positions, and unanimously resolve to render them all the assistance in their power.

Resolved unanimously: That notice be given in the JOURNAL that a fund has been opened in the South of Ireland Branch for assisting the medical men in Cork who have resigned their positions, and that subscriptions be received from members of the Association towards this fund.

Copies of the foregoing resolutions were ordered to be sent to the Branches in the United Kingdom.

Your Council have the pleasure to report to you that the aid that the Association has given to the Cork members is stated to have had the effect of stimulating them to stand by one another in a struggle which affects the whole profession. The question is now one of widespread and general interest, as shown by the number of resolutions which the Cork members have received in support of their conduct.

In accordance with a resolution of the last annual meeting expressing a desire that the Council would constitute an ethical section, the Council have carried the recommendation into effect, and an Ethical Section has been formed for the first time. Your Council trust that you will not be disappointed in the result of the experiment.

The Council have had under consideration the arrangement of times of the annual meeting, and have fixed the first general meeting at 2.30; this gives at least four hours without adjournment for consideration of the various reports and business that may arise. The adjourned evening meeting at 9 o'clock will be devoted to the President's address. The business adjourned from the afternoon meeting (if any) will be considered at the general meeting on Wednesday, after the Address in Medicine. Your Council trust that these modifications of the arrangements will prove satisfactory.

An application was made from the Civil Rights Defence Committee for a donation to their fund for appeal to the Privy Council, from certain judgments of the courts in Tobago and Trinidad for restoration of rights in the case of Mr. Anderson; and, though many of your Council were favourable to such a use of the funds, they considered it desirable to obtain counsel's opinion before making a grant, for if the Council act contrary to the Memorandum of Association, serious penalties may be incurred. The following is a copy of the opinion of counsel:

"I am of opinion that in construing the Memorandum of Association of the British Medical Association, the objects referred to in paragraph (c) of Clause 3 must be held to be the objects specified at the commencement of that clause, namely, 'the promotion of medical and the allied sciences, and the maintenance of the honour and the interests of the medical profession,' but I think that it is so doubtful whether the words in paragraph (c) 'and such other lawful things as are incidental to or conducive to the attainment of the above objects' include things which are not similar to any of the things specified in paragraphs (a), (b), (c), and (d), that the Council cannot be advised to incur the responsibility and risk which, under Clause 6, might, perhaps, be serious, of expending money of the Association on anything which is not so specified, and is not clearly similar to some of the things which are so specified, and consequently that the Council cannot be advised to expend money for any of the purposes referred to in the case.—(Signed) JOHN DIXON, 11, New Square, Lincoln's Inn, May 15th, 1886."

The attention of the Parliamentary Bills Committee has been occupied by many important questions. Among them have been the Registration of Midwives Bill and the Amendment of the Medical Acts; both have been the subject of careful study, and the resulting drafts, which are not yet completed, have been at various stages of their progress, and will further be, submitted for the opinion of the Branches. A special Subcommittee has ultimately been appointed to reduce these drafts into an improved and extended form of Bill, with the help of the amendments suggested by the Branches and of the criticisms of individual members. The question of mortality among the children of women employed in factories has been submitted in detail to the late Home Secretary, and as the result of the series of articles in the JOURNAL on the important question of the health and sanitary

condition of pauper children in great conjoint schools, an independent Commission has been appointed by the President of the Local Government Board, as to the composition of which the Chairman of the Committee was consulted, and his evidence taken at length before the Commission. A great body of evidence has been taken, and an important report, recommending considerable changes, is likely to be submitted at an early date. Pressure had been put upon the Government to accelerate the publication of the report of the Royal Commission on Vaccination, the delay of which has had serious effects throughout the country, but thus far without success. Useful action has been taken in regard to the Poor-law Officers' Superannuation Bill, the Cantonments Acts Amendments Bill, the prevention of cholera, and the Meccan pilgrimage. On these points more detailed information will be found in the report of the Parliamentary Bills Committee.

Last year it will be remembered that there were certain proposals of the Council modifying the arrangements for making grants for scientific research. It was then decided to appoint three scientific scholars instead of two, and a grant of £350 was also made for other research, making the vote for the purposes of the Scientific Grants Committee for the year £725. The three scholars appointed are Dr. Carlwright Wood, of Edinburgh; Dr. Lloyd Jones, of Cambridge; and Dr. Soltau Fenwick, of London.

The persistent work of the Inebriates Legislation Committee for a quarter of a century has been bearing good fruit during the past year. The Home Secretary not having been able to fulfil his intimation to a joint deputation of the Committee and the Society for the Study of Inebriety that he would introduce a Bill into Parliament founded on the report of the Departmental Committee last parliamentary session, the Association Committee presented anew the main improvements in the law which they had urged, especially compulsory curative seclusion, provision for the poorest class of inebriates, and the inclusion of excess in morphine and other drugs, as well as alcoholic intoxicants. The issue has been that the Lord Chancellor has secured the first reading in the House of Lords of the promised measure.

The Bill adopts the chief proposals of the British Medical Association and the Society for the Study of Inebriety: (1) The power of involuntary therapeutic detention of a habitual drunkard is vested in the county court (with right of appeal to the High Court) and the High Court. (2) Provision is made for the poor by power to county councils to establish and maintain retreats. (3) Habitual drunkenness is to include habitual excess in any drug. (4) Voluntary applicants will have to appear before one justice only. (5) Inebriate offenders can, at magisterial or judicial option, be subjected to curative treatment in a reformatory instead of imprisonment in a gaol.

The Scottish Departmental Committee has just issued a valuable and exhaustive report, with proposals for amended legislation, which will provide for the compulsory therapeutic detention of every habitual drunkard. The Departmental Committee on Prisons has reported in favour of the medical treatment of habitual inebriate offenders instead of their present imprisonment, which is stated to be neither elevating nor deterring. The recent Canadian Royal Commission on Intoxicants has reported to the like effect. Thus within the period of two years four Governmental inquiries have resulted in unanimous endorsement of the involuntary remedial treatment of inebriates, a conclusion come to by the Parliamentary Committee of 1872.

The Committee on School Children have worked continuously since 1888 and have examined and reported on 100,000 children, showing among other points the frequency, and to some extent the causation, of defectiveness of body and brain; the constitutional differences between boys and girls; many causes of delicacy, as well as the proportion of the children needing special care and training. Information is afforded as to the conditions of the children of the nationalities and social classes, and much attention has been bestowed upon methods of reporting and studying groups of cases, enabling us to make practical recommendations, which have to some extent been urged upon the Government departments and the London School Board.

The Medical Charities Committee have extended the move

ment against the abuse of medical charities to the provinces, and have communicated with all the Branches of the Association, many of which have responded sympathetically, and have promised an investigation and a report upon the subject.

Since the reappointment of the Anæsthetics Committee at the last annual meeting, the work of analysing the records—deputed to a subcommittee—has been steadily continued. The subcommittee, assisted by a staff of clerks, resumed their meetings in October, 1894, and from that time till the present date have met on 67 occasions, each meeting lasting at least two hours. Upwards of 23,000 uncomplicated cases have been submitted to an elaborate scheme of tabulation and cross tabulation.

The Committee for the Efficient Control of Railway Servants' and Mariners' Eyesight continues its labours. It organised an important deputation of ophthalmic surgeons, which waited upon the President of the Board of Trade on February 1st, and by thus bringing the subject entrusted to it prominently before the authorities and the public, is able to report that, though much remains to be done before efficient control can be said to have been secured, more attention is now being paid to the eyesight of these classes.

The Therapeutic Committee present a short interim report. In asking you to express your cordial thanks to the Honorary Secretaries of Branches for their voluntary but arduous labours during the past year, your Council would point out the increase in the number of members of many of the Branches, and the joint interesting meetings for the discussion of questions of medical and surgical science and medical policy which have been organised.

Amongst the changes that have occurred, Dr. Peter Bancroft has retired from the Honorary Secretaryship of the Brisbane and Queensland Branch, Dr. E. D. Rowland from the British Guiana Branch, Dr. Damian from the Trinidad and Tobago Branch, Dr. Anderson from the Cape of Good Hope Branch, Dr. Freeland Fergus from the Glasgow and West of Scotland Branch, Dr. H. A. Lafleur from the Montreal Branch, Dr. J. G. Cooke from the Londonderry Branch, Dr. H. W. Pigeon from the East York and North Lincoln Branch, Dr. John Molony from the Dublin Branch, Dr. J. Altham from the Border Counties Branch, and Dr. E. Markham Sheritt from the Bath and Bristol Branch, while your Council have to regret the loss by death of Dr. J. Bigg Robertson, of the Grahamstown Branch. The following gentlemen have been elected respectively to fill the vacancies: Dr. A. B. Brockway, Mr. C. W. Daniels, Dr. E. Prada, Dr. D. J. Wood, Dr. J. H. Nicoll, Dr. J. A. Springle, Dr. E. Donaldson, Dr. J. B. Close, Dr. James Craig, Dr. R. Dundas Helm, and Dr. J. Mitchell Clarke; while Dr. Caldwell has been elected to fill the vacancy caused by the death of Dr. Robertson. In March, 1894, upon the retirement of Dr. E. J. Jenkins from the Honorary Secretaryship of the Sydney and New South Wales Branch, Dr. L. R. Huxtable was appointed.

Amongst those who have passed away during the year, your Council have to mourn the loss of Dr. Withers Moore, who was President in 1886, when the Association met at Brighton. He was President of Council from 1890 to 1893, and was a Vice-President at the time of his death. Dr. George Henty, a Vice-President of the Metropolitan Counties Branch, whose services on the Medical Charities Committee will be remembered; Dr. Bevan Rake, late President of the Trinidad and Tobago Branch; Mr. John Orerar, a Vice-President of the Border Counties Branch; Mr. Arthur Durham, a former President of the Metropolitan Counties Branch, who was appointed to give the Address in Surgery at this meeting. Also Mr. David Davies, of Abercree, who was President of the Public Health Section at the annual meeting of the Association held in Bath in 1878; Brigade-Surgeon G. C. Gribbin; Mr. S. Wm. North, of York, who was President of the Yorkshire Branch; Mr. Wm. Lees Underhill, of Tipton; Dr. Robert Jolly, of Birmingham; Mr. John Clay, of Birmingham; Mr. John Brockwell, of Norwood; Mr. J. Capron Smith, of Great Yarmouth, who was President of the East Anglian Branch; Dr. Andrew Miller, of Hampstead; Dr. Herbert Goude, of Highgate; Dr. W. Joseph Lunn, of Hull; Inspector-General Mark Style, of Cheltenham; Mr. Charles E. Thompson, of South Australia; Mr. Robert McNicoll, of St. Helens; Dr. Waldemar I. Roedel, of Melbourne; Dr. Walter

Dickson, R.N., of Upper Norwood, late Honorary Treasurer to the Metropolitan Counties Branch, whose face and genial manner were so familiar to those attending the annual meetings; Mr. Albert Napper, of Guildford, the great authority on cottage hospitals; Deputy Surgeon-General E. Humphrey Roberts; Dr. Wm. Walker, of Reading; Mr. W. Palmer Rowe, of Liverpool; Dr. J. J. Neville, of Chelmsford; Mr. A. W. Loveridge, of Newport, Mon.; Mr. Robert Farrer, of Brig-house, Leeds; Dr. James Hall, of Preston; Mr. Philip G. Phillips, of Peckham; Dr. H. W. Maunsell, of London; Dr. T. T. Hamilton, of Bury; Dr. D. Hack Tuke, of London; Dr. S. H. Adams, of Bedford; Mr. M. H. Higginbottom, of Nottingham; Mr. Charles H. Robinson; Dr. T. A. G. Balfour, of Edinburgh; Mr. G. T. Lee, of Salisbury; Mr. Daniel Ball, of Stoke-on-Trent; Mr. James H. Coveney, of Frestwich; Dr. W. J. Cleaver, of Sheffield; Deputy Surgeon-General S. S. Skipton, of Liscaud; Brigade-Surgeon-Lieutenant-Colonel J. D. Gunning, A.M.S.; Mr. Harris Butterfield, of Sevenoaks; Mr. G. G. Corbould, of Bristol; Dr. A. E. Turner, of Denbigh; Dr. G. E. Alford, of Weston-super-Mare; Dr. J. S. Metford, of Clifton; and Dr. Robert K. Johnston, of Dublin.

J. WARD COUSINE, M.D.,

President of Council.

INTERIM REPORT OF THE COMMITTEE ON THE COMPLAINTS OF GENERAL PRACTITIONERS.

IN consequence of a feeling expressed by many members that something should be done to correct the grievances of general medical practitioners, and also in consequence of a resolution which had been passed by the East Sussex District of the South Eastern Branch, copy of which is as follows:

Resolved: That in view of the prevalent and widespread feeling that the Executive of the Association are not alive to the wants and misfortunes of the general practitioners, and do not, therefore, render them such assistance as they, being members, have a right to expect, this meeting respectfully requests the Council to appoint a Committee (1) To inquire into the grievances, wants, and requirements of the general practitioners, as they are found to exist in the Branches of the Association. (2) To ascertain in what ways, if any, the influence and organisation of the Association can be most usefully employed for the amelioration of these grievances, and for promoting the welfare of the general practitioners generally. (3) To report to the Council.

The Council at their October meeting passed the following resolutions:

Resolved: That the resolution passed at the East Sussex District of the South Eastern Branch having been duly considered by the Council, the request therein contained be granted, and a committee appointed to carry out the suggestions.

Resolved: That the President of Council, Dr. Bridgwater, Mr. Wallace, Dr. Bruce Goff, Mr. Jones Morris, Mr. Nicholson, Dr. Saundby, Mr. Parkinson, Dr. Parsons, and Dr. Withers Moore be appointed the Committee to consider the preceding resolution.

At a subsequent meeting of the Council the Treasurer of the Association and Mr. Hemming were added to the Committee.

Resolved: That the question of medical aid associations, brought forward by the Oxford and District Branch, be referred to the Committee to report to this Council at the earliest possible date.

The Committee of the Council decided to inquire into the following subjects for consideration in the first instance:—

1. Cheap Anonymous Dispensaries and Medical Aid Societies.
2. Midwives.
3. Pay Wards of Hospitals.
4. Lack of Competent Assistants.
5. Insecurity of Local Sanitary Appointments.
6. Inadequacy and Uncertainty of Retiring Pensions of Poor Law Officers.
7. Alteration of Memorandum of Association so as to permit funds to be used for Medical Defence and Prosecution of Quacks, Bonesetters, and Prescribing Chemists.

8. Underselling for Public Appointments.
9. Relations of Consultants to General Practitioners.
10. Censorship of Association.

It will be obvious to any member who has given consideration to the work of the Committee that to investigate and to report fully upon these ten subjects would take much longer than the few months which have been at their disposal; they therefore offer this as an interim report.

ANONYMOUS DISPENSARIES.—The attention of the Parliamentary Bills Committee has been called to the question, and the Committee was requested to insert a clause in the Medical Acts Amendment Bill rendering it compulsory to announce the name of the responsible medical officers to such establishments.

MEDICAL AID SOCIETIES.—The Committee understands by this title those societies or clubs which have been recently established for the purpose of affording medical attendance, etc., in return for a small annual subscription. The proprietors are laymen, the doctor is paid a fixed salary, and the balance of the income is appropriated for investment or other purposes. These societies do great harm to the established practitioners by their system of canvassing for members among all classes. It is greatly to be regretted that any qualified practitioner should become the instrument of a system which is lowering the prestige and position of the profession in many parts of the country, and in the opinion of this Committee the medical officers of such societies as canvass for members and have no wage limit should not be elected, or if elected should not remain, members of the British Medical Association.

MIDWIVES.—The question of midwives has been fully considered, and it is felt that the employment of midwives other than skilled nurses is fraught with danger to the public and injustice to the qualified practitioner. Your Committee passed the following resolution, which was transmitted to Sir Walter Foster:

That inasmuch as the proper care of parturient women before, during, and after labour involves a knowledge of almost the whole art of medicine and surgery, no one should be entrusted with this care save fully trained and qualified practitioners; at the same time, there is a general demand for an improved class of trained midwifery nurses.

As a Bill for the registration of midwives has been before Parliament, and as the movement is supported by no inconsiderable body of lay and professional opinion which will not rest satisfied with things as they are, this Committee recommends the Council to endeavour to formulate and agree upon a scheme for the training and registration of all classes of nurses, among which those who, in addition to their regular hospital training, shall have qualified by a special course of instruction at a lying-in hospital, will be registered as obstetric nurses.

Your Committee believes that the dangers to be apprehended from the legislative recognition of midwives would by this scheme be reduced to a minimum, while the class of women so trained would be most efficient for the purpose for which they are required. Nothing could be worse than the present system, and, in the opinion of this Committee, the General Medical Council has only done its duty to the profession by the firm stand it has made against the illegal traffic in midwifery diplomas.

PAY WARD.—This question has been left for the present, as it is under the consideration of the Medical Charities Committee and also a Committee of the Council of the Metropolitan Counties Branch.

LACK OF COMPETENT ASSISTANTS.—The information on this head which has reached your Committee has not been sufficient to enable an opinion to be formed as to the causes of the deficiency. That there should be such a difficulty is surprising in view of the other painful evidences of the increasing competition within the profession, and would appear to point to the need for making these appointments more attractive to the better class of men by improving the conditions under which they are held.

The Committee is strongly of opinion that all assistants employed by practitioners should be duly qualified medical men.

It is hoped that the recommendation of the General Medical Council that students should take the last year of their curriculum with a general practitioner will do some-

thing to remedy the present want of experience of the details of general practice among recently qualified medical men.

INSECURITY OF SANITARY APPOINTMENTS.—With regard to this question, the President of Council, with others, had an interview with Sir Walter Foster, of the Local Government Board, who stated on behalf of the Board that an important decision had been arrived at, namely, that short periods and precarious tenure of office are injurious to the public health, and the Board are anxious to encourage the authorities everywhere to give up the system of short terminable appointments.

INADEQUACY AND UNCERTAINTY OF RETIRING PENSIONS OF POOR-LAW OFFICERS.—In considering this, your Committee found that a Bill to provide for the superannuation allowances to Poor-law officers and servants, which your Solicitor was of opinion also included Poor-law officers, had been prepared and brought in by Mr. Walter Long, M.P., and others, and accordingly a petition was signed on behalf of the Association by the President, Dr. Long Fox; the President-elect, Sir Russell Reynolds, Bart.; the President of Council, Dr. Ward Cousins, and the Treasurer, Mr. Biffin. The petition was kindly presented by Sir Walter Foster of the Local Government Board. Mr. Shaw Lefevre, on the part of the Government, expressed a favourable view upon the second reading, but as the Bill was opposed the second reading was postponed. In the meantime your Committee trusts that the Branches will endeavour to influence local members of Parliament to support the Bill.

MEDICAL DEFENCE AND THE PROSECUTION OF UNQUALIFIED PERSONS.—The suggestion has been made that these duties should be assumed by the British Medical Association. The Committee has the very strongest sympathy with the large body of members which complains of the unprotected condition of the medical profession, and desires to see constituted some authority provided with the means and charged with the duty of protecting the profession and the public against injustice, ignorance, and fraud. Unfortunately there are many difficulties in the way; in the first place the present law only penalises the improper assumption of medical titles and the unqualified practice of medicine where the unqualified person not only prescribes but compounds and supplies medicine for gain, while it permits surgical practice to be carried on to any extent by ignorant persons. Secondly, there are no funds for this purpose except those of voluntary associations for medical defence, which have undertaken useful action of this kind to a limited extent. Thirdly, although any person may take proceedings for the unqualified assumption of medical titles, there is no authority empowered in respect of the unqualified practice of medicine except the Society of Apothecaries, which in many instances is unwilling to proceed of its own motion, although it permits its name to be used upon the understanding that it should be put to no expense. Fourthly, there is always very great difficulty in getting evidence upon which conviction can be obtained, even in some of the most flagrant cases of illicit practice.

The Medical Acts Amendment Bill, drafted by the Parliamentary Bills Committee, will, if it becomes law, strengthen considerably the hands of future prosecutors, and the whole influence of the Association should be employed to secure its enactment.

It is not easy to devise a plan under which these duties could be performed by the British Medical Association.

Is it proposed that the Association should defend its members and prosecute quackery all over the world? If so, the proposal is plainly impracticable, and beyond the means of our organisation. On the other hand, if it is intended to limit these benefits to members residing within a certain area, the proposal is open to the fatal objection that it would apply general funds to local purposes, and would be naturally unfair to those whose property would be endangered without benefit to themselves.

One suggested alternative is to raise a separate fund for local purposes by voluntary subscriptions to be administered for the benefit of subscribers, but such an organisation could not take legal action without risk of contingent liability falling upon the funds of the parent Association, unless it was made quite clear that there was no real connection between the two; and if this were the case it is difficult to see what advantage the plan offers over existing arrangements.

It also has been proposed to subsidise one of the existing medical defence associations by a grant from the funds of the Association to be used for specific purposes. But this scheme would probably fall far short of satisfying the demands of many, and is equally open to the capital objection which applies to all these proposals—namely, that they are outside the objects of the Association as at present constituted, and can only be included by altering the Memorandum of Association. Upon this point the Committee has sought the advice of counsel, whose opinion is subjoined:

COPY OF COUNSEL'S OPINION.

I am of opinion that in construing the Memorandum of Association of the British Medical Association the objects referred to in paragraph (e) of Clause 3 must be held to be the objects specified at the commencement of that clause—namely, "the promotion of medical and the allied sciences and the maintenance of the honour and the interests of the medical profession;" but I think that it is so doubtful whether the words in paragraph (e) "and such other lawful things as are incidental to or conducive to the attainment of the above objects" include things which are not similar to any of the things specified in paragraphs (a), (b), (c), and (d), that the Council cannot be advised to incur the responsibility and risk which under Clause 6 might perhaps be serious, of expending money of the Association on anything which is not so specified and is not clearly similar to some of the things which are so specified, and consequently that the Council cannot be advised to expend money for any of the purposes referred to in the case.

JOHN DIXON.

May 14th, 1895.

11, New Square, Lincoln's Inn.

The Committee does not recommend this alteration of the Memorandum of Association for the following reasons:

1. No such change should be proposed by the Council until it has been well considered in all its bearings, and unless there is good reason to believe that the Association would be practically unanimous in supporting it.

2. The change is one which is radically inconsistent with the objects for which the Association was originally founded.

3. It is impossible, therefore, to assume that an alteration in the Memorandum of the Association involving such a change would be permitted, and unless permitted such a fundamental alteration in the constitution of the Association would be impossible without liquidation and reconstruction.

4. The change would involve the Association in consequences not easily foreseen; for example, it might render it liable to taxation from which it is at present exempted as a scientific body.

5. It has been already shown that there are real practical difficulties in the way of making such extended functions coextensive with the whole sphere of operations of the Association or of limiting them to a part of its area; nor is it easy to devise any plan by which a fund could be raised and administered for this purpose without risk of liability to the corporate body.

For these reasons, and after due consideration, the Committee recommends that it is not desirable to seek to alter the Memorandum of Association for these purposes.

Another suggestion, and one which meets with the approval of the Committee, is that the Association should endeavour to get part of this duty imposed by statute upon the General Medical Council.

This would follow the precedent of at least one of our Colonies, as described in the following letter from Dr. J. M. Lefevre:

12, Duchess Street, Portland Place, W.,

April 20th, 1895.

Dear Sir,—In reference to our conversation of Tuesday last, I may state that in British Columbia licences to practise medicine and surgery are granted by the British Columbia Medical Council. This authority is vested in the Council by an Act passed some seven or eight years ago by the Legislature of the province. This Act is known as the British Columbia Medical Act, and it gives the Council power to make rules and regulations for the granting of licences to graduates in medicine and surgery of any recognised University. It also gives the Council power to fix the annual fee and the fee for registration. The former fee at present is 5 dollars, and the latter 100 dollars. The revenue derived

from these sources is used by the Council principally in defraying the expenses of examinations for licence to practise and for legal expenses in connection with the prosecution of illegal practitioners. I shall be very glad to give you any further information you may require on this subject at any time.—Yours very truly,

J. M. LEFEVRE.

FRANCIS FOWKE, Esq.,

General Secretary, British Medical Association.

As at present constituted, the General Medical Council does not adequately represent the medical profession. It is mainly composed of the representatives of what may be called the privileged classes of the profession, and falls far short of what is needed as a central governing body. Its reform may be a difficult task, but it is certain that the profession will never be able to make its views and wishes properly felt so long as this Council remains as it is, and the Committee urges the importance of making this great reform a main policy of the Association. The Committee is glad to learn that the Parliamentary Bills Committee has also recognised the need for such a step, and is considering the possibility of tacking on a clause to its Medical Acts Amendment Bill with this object.

UNDERSELLING FOR PUBLIC APPOINTMENTS: RELATION OF CONSULTANTS TO GENERAL PRACTITIONERS.—The Committee has unavoidably been compelled to postpone any special report upon these important subjects from want of time, but it is desirable to point out that most of the questions arising under these heads might be dealt with by local Ethical Committees, which could report any flagrant cases of misconduct to the Council in the usual manner. The Committee recommends the formation of such local Ethical Committees in connection with the Branches, and believes that, rightly constituted, they will be productive of much benefit.

CENSORSHIP OF THE ASSOCIATION.—The Council possesses the power to consider any complaint against members respecting acts derogatory to the profession, and has passed motions of expulsion in suitable cases. As there is no reason to believe that the Council is unwilling to exercise the ample powers of censorship it already possesses, the Committee has only to point out that it rests with the Branches to make these powers effective by reporting all serious cases of professional misconduct to the Council for censure or expulsion.

The Committee asks to be reappointed.

J. WARD COUSINS, M.D., President of Council.

REPORT OF PARLIAMENTARY BILLS COMMITTEE.

MANY matters of very considerable importance, both to the profession and to the public, have occupied the attention of the Parliamentary Bills Committee during the past year. Some, such as the amendment of the Medical Acts and the standing question of Vaccination, have been matters of perennial interest for years past, and, it is to be feared, will not attain a final settlement for years to come; others have been affairs of great but more or less ephemeral importance.

AMENDMENT OF THE MEDICAL ACTS.

The position of affairs at the beginning of the year was this: The Chairman had been authorised to submit certain documents in the possession of the Committee to counsel, and to prepare a draft Bill based upon the reports received from the Branches. In order to give weight to the remarks made upon the subject during the discussion upon it at the Bristol meeting he had also sent copies of the speeches made on the subject, lest any point which had been raised should chance to be overlooked.

As the result of this reference to counsel a draft was sent in, which, however, was not considered to cover a sufficiently large field, being, in fact, principally limited to a reconstruction of the penal clauses. After further consideration and consultation the basis of the memorandum was considerably widened, the principal point left out being the question of medical aid associations which were employing medical men and making a profit out of their work.

On the draft being submitted to the Committee, it was resolved that the documents submitted should be forwarded to each of the Branches with a request for any further observations thereon.

The Branches were also asked to call general meetings for the discussion of the matter, and to let the Committee have their observations early in the year.

At the meeting of the Committee held in April it was reported that some of the Branches had replied approving of the Bill, others had not replied, while some had replied offering suggestions and additions. Most of these suggestions required further consideration as to whether they were possible, and on submitting them for legal comment the Committee were advised that it would be well to deal with each of the suggestions made by the Branches separately and fully. Several members of the Committee, however, thought that they ought to have an opportunity of discussing the provisions of the draft as it stood, and various comments and criticisms were made upon it, especially in regard to its inadequacy in the important matter of dealing with these unqualified persons who practised without assuming any qualification. It was stated that the Medical Defence Union had great difficulty in prosecuting in these cases, as most of the persons did not assume any title at all, and thus escaped the operation of the Act, and that it was imperative that the Bill should be altered so as to include a clause to control this form of unqualified practice.

After some further discussion, it was proposed by Mr. Victor Horsley, seconded by Dr. Batten, and resolved:

That the draft Bill, together with the amendments and suggestions forwarded by the Branches, be handed to a Subcommittee, with power to take such legal advice as may be necessary to redraft the Bill where thought desirable.

The following subcommittee was appointed to consider the draft Bill to amend the Medical Acts: The Chairman, Dr. Batten (Gloucester Branch), Dr. Spottiswoode Cameron (Yorkshire Branch), Dr. Galton (South-Eastern Branch), Mr. Victor Horsley (Metropolitan Counties Branch), Mr. Evan Jones (North Wales Branch), Dr. Somerville (Border Counties Branch), and Dr. Woodcock (Lancashire and Cheshire Branch).

After some discussion, it was proposed by Dr. Milburn, seconded by Mr. Taylor, and resolved:

That the subcommittee also report on the advisability and practicability of including in the draft Bill the subjects of—(1) The constitution and powers of the General Medical Council; (2) the penal powers of the medical corporations and universities in respect of the conduct of their medical graduates and diplomates; (3) certificates and registration of dentists.

This Committee has since been actively occupied in the performance of these duties.

MORTALITY AMONG CHILDREN OF WOMEN EMPLOYED IN FACTORIES.

At the first meeting of the Committee it was reported that no progress had been made in this matter, except that Mr. Asquith had promised to receive a deputation on the subject from the Committee early in November. A full statement was made to Mr. Asquith, to which, however, he did not give a very sympathetic reply. It is hoped, however, that some of the provisions of the new Factory and Workshops Bill will have a good influence in the desired direction.

BARRACK SCHOOLS.

With reference to this question, the Chairman reported that he had had several interviews with Mr. Shaw Lefevre, who probably would have granted the Royal Commission which was asked for by the joint deputation which waited upon him, but for the feeling that by so doing the matter might be hung up for two or three years. Finally, an independent Committee under the chairmanship of Mr. Mundella, has been appointed as the result of which great reforms were hoped for. That Committee, which was nominated after a conference with the Parliamentary Bills Committee, is powerfully constituted. The first evidence taken was that of the Chairman of this Committee. Much evidence has since been taken, and an important report may forthwith be expected.

CHOLERA AT HARDWAR AND MECCA.

The subject of the distribution of cholera by land and sea has been discussed by the Committee and steps are being taken to bring the facts in regard to the Mecca pilgrimage under the cognizance of the Sultan by the intervention of the

Mohammedans themselves. Mr. Hart's visit to India was followed by important resolutions passed at great public meetings of Mussulmans in Calcutta and Hyderabad, calling for reforms (much needed) at the quarantine stations at Mecca.

VACCINATION.

The great evils which were being caused by the delay in the issuing of the report of the Royal Commission on Vaccination were brought before the notice of the Committee. It was pointed out that the Commission had been sitting for five years, and that a great many Boards of Guardians had decided not to prosecute in cases of non-compliance with the Vaccination Acts pending the issue of the Commission's report.

Mr. Galton proposed, and Dr. Holman seconded, the following resolution, which was carried unanimously:

That the Parliamentary Bills Committee greatly regret the delay in the issuing of the final report of the Vaccination Commission, and trusts that the Commission will issue it at the earliest possible date. Should it be impossible to issue a detailed report soon, they hope the Commission will, at any rate, issue an interim report, so as to set at rest all doubts as to the value of vaccination.

The preoccupations of the Chairman and other members of the Commission, and the special inquiries instituted at the seats of the epidemic in 1893-94, have, however, caused further delay, and the date for the presentation of the report is not yet fixed.

THE ARMY MEDICAL DEPARTMENT.

The Chairman received in February last the following letter from the War Office:

War Office, Pall Mall, S.W.,
February 15th, 1905.

SIR.—Adverting to my communication of August 24th, 1904, and to that section thereof in which it was stated that the question of posting officers of the British Medical Service to particular Presidencies for duty was reserved for further consideration, I am now directed by Mr. Campbell-Bannerman to acquaint you, for the information of the Parliamentary Bills Committee, that it has been decided, with the concurrence of the Secretary of State for India in Council, to revert to the former system, whereby the allocation of medical officers proceeding to India was carried out in this country. I am, however, to add that, consequent upon impending changes in Indian army organization, postings will be made to commands instead of to presidencies, and the allocation of officers to the several commands will be subject to such occasional transfers as the exigencies of the service in India may dictate. I have the honour to be, Sir, your obedient servant,

RALPH THOMPSON.

The Chairman of the Parliamentary Bills
Committee of the British Medical
Association, 499, Strand, W.C.

POOR LAW OFFICERS SUPERANNUATION BILL.

The question having arisen whether the Poor-law Officers Superannuation Bill introduced into the House of Commons included Poor-law medical officers, the opinion of the solicitors had been taken on the point, and they had replied that the Bill did not include the medical officers. It was then proposed by Mr. Jones Morris, seconded by Mr. Parkinson, and resolved:

That the Parliamentary Bills Committee strongly supports the Bill, and requests the members of the Branches to interview their members of Parliament with the view of getting them to use their influence in getting the Bill through Parliament.

CANTONMENTS ACT AMENDMENT BILL.

In this Bill a clause was included which was highly dangerous and derogatory to army medical officers. Not only were they ordered not to do certain things, but if they did not carry out the orders they were not dealt with by their own department, but were liable to be taken before a magistrate, and they were to be punishable by the civil jurisdiction. The Chairman reported that he was able just in time to make a very strong protest in India at the request of the Indian men, who, as officials of the Government, could do nothing. He saw Sir Anthony MacDonnell on the subject, telegrams were sent to this country to the India Office of a very urgent nature, and a meeting was called to make arrangements for a deputation to Mr. Fowler, but before the meeting could be held Mr. Fowler withdrew the whole of the objectionable clause. That result gave very great satisfaction in India, and tended a great deal to the credit of the British Medical Association.

Other subjects dealt with during the year included legisla-

tion for the regulation of massage houses, which is held over till next year, and suggested alterations and additions to the Factory and Workshops Bill.

MIDWIVES REGISTRATION BILL.

Subsequent to the meeting of the Parliamentary Bills Committee, held on May 30th, 1895, the Chairman referred the Midwives Registration Bill to the Subcommittee appointed to consider the draft Bill to amend the Medical Acts, and also that the Midwives Registration Bill be considered first. The Bill was considered clause by clause, and certain amendments were made, the principal ones being the substitution of the term "midwifery nurse" for that of "midwife" in certain clauses, and the insertion of a provision in Clause 4 that a woman registered under the Act shall not assume any title implying that she is by law recognised as a licentiate or practitioner in midwifery except in cases of natural labour. All documents on the subject in the possession of the JOURNAL have been submitted to this Committee, whose interim report has been issued to all the Branches.

ENNET HART, *Chairman*.

REPORT OF THE SCIENTIFIC GRANTS COMMITTEE.

The Scientific Grants Committee have to report that during the past year, 1894-5, the sum of £349 16s. 6d. has been granted in aid of scientific research, and £450 for three scientific scholars. The following are particulars of the grants made:

	£	s.	d.
BRODIE, T. G., M.D., Lindfield, Uxbridge Road, Surbiton.—To complete and extend a work on the chemistry of cancerous tumours of fibroid degenerations; and for the purchase of new apparatus constructed for the study of the amount of work performed by muscles under varying conditions.	30	0	0
COOPER, G. D., M.R.C.S., County Asylum, Uxbridge, Woodford, Essex.—An investigation on the subject of the metabolism in general paralysis of the insane.	5	0	0
GILLMIST, A. L., M.D., 23, Walker Street, Edinburgh.—For the purpose of testing the action of alkalies and acids on that of the pancreas and intestines.	10	0	0
GRONAU, ALBERT E., M.B., 45, Ladbrooke Grove, W.—For an investigation into the cutaneous distribution of the peripheral nerves in the monkey. (Wrote for amount June 13th, 1894.)	10	0	0
HALLIBURTON, W. D., M.D., F.R.S., 9, Ridgmount Gardens, Gower Street, W.C.—To continue research work on the proteid constituents of animal tissues.	25	0	0
HARRIS, A. BUTLER, M.B., 189, High Street, Newington, N.—For an investigation on the processes of oxidation in the various tissues and organs, the relative degree of the same, and the alterations in disease.	20	0	0
HAYWARD, JOHN A., M.D., 65, Brook Street, W.—(1) For an investigation to improve, if possible, our means of culturing the diphtheria bacillus, whereby the diagnosis of disease bacteriologically may be facilitated. (2) To test the action of certain drugs and ferments in the diphtheria bacillus. (3) To examine a series of cases of membranous sore throats, whether simple, scarlatinal, or diphtheritic, and to determine their relation to the diphtheria bacillus.	10	0	0
HEWLETT, R. T., M.D., 141, Great Russell Street, W.C.—To defray expenses to be incurred in the completion of the research on the chemistry of cancer.	4	14	6
HORNE, R. M., M.B., Physiological Laboratory, The Owens College, Manchester.—For an investigation on muscle. (1) The nature of the muscle ferment. (2) The influence of calcium salts on the coagulation of muscle. (3) The existence of a myoalbumose.	5	0	0
KANTHACK, A. A., M.D., St. Bartholomew's Hospital, E.C.—To continue a research on the nature and behaviour of wandering cells.	15	0	0
KENT, A. F. S., Physiological Department, St. Thomas's Hospital, S.E.—For a continuation of an investigation upon the functions of the thyroid gland.	15	0	0
LAZARUS-BARLOW, WALTER S., M.D., Pathological Laboratory, New Museum, Cambridge.—(1) The oedema which accompanies inflammation. (2) The physiological action of the diphtheria toxin on the heart.	20	0	0
LEVY, A. G., M.B., 189, High Street, Stoke Newington, N.—For a research to investigate the elastic recoil of the living brain after compression for varying lengths of time, and to establish the vascular conditions which have an influence upon the brain's elasticity.	10	0	0
MORR, F. W., M.D., 84, Wimpole Street, W.—For a continuation of a research upon the functions and structure of the central nervous system.	20	0	0
MUIR, RONNIE, M.D., 20, Hartington Place, Edinburgh.—(1) An inquiry into the nature of leucocytosis. (2) An inquiry into the changes in the lymphoid tissues during leucocytosis.	10	0	0
MURRAY, G. R., M.B., 2, Saville Place, Newcastle-upon-Tyne.—To continue an investigation into the active substances contained in the secretion of the thyroid gland.	15	0	0

PEMBREY, M. S., M.B., Physiological Laboratory, Oxford.—For a continuation of a research upon the effect of section of the spinal cord and of anesthetics upon the reaction of changes of temperature.	10	0	0
SAMWAYS, D. W., M.B., 8, Rue Dauphine, Montpellier, France.—(1) To demonstrate the physical cause of the wave. (2) To investigate the time relation in the contraction of the left auricle and ventricle, when the former is hypertrophied in cases of mitral stenosis.	20	0	0
SHENMAN, T., M.B., 71, Leamington Terrace, Edinburgh.—For continuing a research on callos edulis.	5	0	0
SMITH, HUGH R., M.D., Pathological Laboratory, University College Hospital, W.C.—For an investigation into the nature of the various exudations and transudations found within the body. (a) Special attention will be given to the examination of the different forms of fluid found in the various cysts originating within the female pelvis. (b) The investigation of pleuritic, ascitic, oedemic, and other fluids.	20	0	0
STILES, W. L., M.R.C.S., 39, Bromdenbury Villas, N.W.—For continuing his work on nerve section.	10	0	0
TENNY, A. H., M.B., F.R.C.S., 39, Finsbury Circus, E.C.—For an investigation on the effect of stimuli on the pleural and peritoneal membranes. Observations to be made on heart, blood pressure, and respiration by the application of heat, cold, various antiseptic substances, etc.	10	0	0
VINCENT, SWALE, M.B., Mason College, Birmingham.—For prosecuting a research upon the physiology of the suprarenal capsules. To purchase $\frac{1}{2}$ inch oil immer. lens (by Zeiss). To purchase microspectroscope.	10	0	0
WENSTON, J. C., M.D., 20, Charlotte Square, Edinburgh.—For the following researches—(1) The place of fertilisation of the ovum. (2) External and internal wandering of the ovum. (3) The reaction of the peritoneum to the fertilised ovum, involving the consideration of the question of primary abdominal gestation.	20	0	0
WHITE, A. H., L.R.C.P.I., 81, Grosvenor Square, Rathmines, Dublin.—For a research in connection with the changes in the composition of the blood in traumatic anæmia.	20	0	0
WHITE, W. HALE, M.D., and WASHBOURN, J. W., M.D., 65, Harley Street, W.—For expenses in connection with the working of their animal calorimeter. (Pamphlet submitted being a reprint of a report from the <i>Journal of Physiology</i>).	10	0	0
Total	349	16	6

Dr. J. JACKSON CLARKE, loan of $\frac{1}{2}$ inch Zeiss water immersion objective.

The following sums have been returned as unused:—

Dr. A. I. Gillespie	5	9	4
Dr. A. E. Grünbaum	5	5	6
Dr. J. A. Hayward	5	2	6
Dr. R. T. Hewlett	0	13	9
Dr. E. Muir	6	17	4
Dr. G. Murray	15	0	0
Dr. M. S. Pembrey	5	7	3
Dr. D. W. Samways	18	2	3
Dr. T. Shenman	1	5	3
Dr. A. H. Tubby	5	14	6
Dr. J. C. Webster	30	0	0
Total	93	1	1

The gentlemen appointed as scientific scholars are Dr. SOLTAU, FENWICK, Dr. LLOYD JONES, and Dr. CARTWRIGHT WOOD.

Dr. T. G. BRODIE reports that during the past year he has been engaged in continuing his research upon the work of muscle. A preliminary report, giving a description of the method he has devised for the purpose of these experiments, has already appeared in the *Proceedings of the Physiological Society*, February, 1895. They are now nearly completed, and a full paper of the results obtained will shortly be ready for publication. He has also been engaged in investigating the differences in the behaviour of collagen and gelatine when treated with alcohol. This has led him, after an examination of Siegfried's work and description of the isolation of a new substance—reticulin—from reticular tissue, to search for some of the products obtained on the decomposition of these two bodies under the action of hydrochloric acid in the presence of stannous chloride. This work is now nearly completed. He has also continued his work upon the constitution of the envelopes of the coccidia frequently found in rabbits' livers, which was undertaken with a view to the examination of cancer tumours for a similar substance. He has been able to show that these envelopes are neither chitin nor cellulose, but as yet he has not been able to obtain these envelopes isolated from nuclein, etc. He is at present engaged upon this work.

Dr. J. JACKSON CLARKE has submitted the following abstract of some observations on an affection of pigeons and fowls, and states that among pigeons and fowls an acute and usually fatal disease, which is termed by poultry rearers "canker," is not uncommon among birds kept in captivity.

The affection begins as a rule in the mouth, on the hard palate, and elsewhere. For twenty-four or forty-eight hours it shows itself by the presence of a yellow soft coating on the mucous membrane. This yellow substance can at first be scraped off, and leaves a red moist surface beneath it. Examined under the microscope the yellow substance is seen to consist almost entirely of flagellate protozoa in active movement. The bodies of organisms are a little larger than the red blood corpuscles of pigeons, and present at one extremity one or more, rarely two, strong flagella as long as their body, and at the opposite extremity a sharp-pointed process about half as long as the flagellum. Along one side of the oval body these protozoa possess an undulating membrane, and in their interior are a nucleus and several vacuoles. Dr. Clarke was unable to find these organisms in the mouth of birds free from the disease. After two days the lesions are changed in character, and are replaced by tough yellow infiltration of the mucous membranes and submucous tissue. In this infiltration only a few moving flagellates are to be found, but sections reveal beaded hyaline bodies which resemble the figures given by Kartulis¹ of protozoa in sections of livers containing abscesses secondary to dysentery. The affection spreads from the mouth to the skin of the eyelids and other parts of the face. In the lesions in this situation histological examination reveals in the epidermal cells bodies in every way similar to molluscum contagiosum of man. So far the observations are in accord with those of L. Pfeiffer.² In the cases Dr. Clarke observed he has failed to find tubercle bacilli either in the earlier or later stages of the affection. He hopes to continue the investigation by inoculation experiments in order to decide finally whether the disease is connected with tuberculosis, and also to ascertain if possible whether the protozoa are the caused agent in producing the affection.

Mr. DUNLEY COOPER reports that his observations were made on the metabolism of general paralysis of the insane, with a view of ascertaining the cause of the great wasting that takes place so constantly in this disease. A typical general paralytic was fed on a mixed diet containing 15.8 grammes of nitrogen; his urine and faeces were analysed for the total nitrogen by Kjeldahl's method. The result of the investigation showed, during the early period of observation, there was an increased elimination of nitrogen due to a deficient absorption of proteids, and as the case progressed the analysis showed that not only was there a diminution in the power of proteid absorption, but also a destruction of the tissue proteids.

Dr. A. L. GILLERIE has been engaged during the past year in testing the action of alkalies and acids on that of the pancreas and intestines; he states that he has now reached the middle of the first series of experiments, a full report of which he hopes to publish during next year.

Dr. A. S. GIESSEN reports that only a few observations, owing to pressure of other work, have been made by him. These were on the ulnar nerve, and tended to show that its sensory distribution in the monkey is more limited than generally supposed. He hopes to continue the investigations with greater rapidity during the coming year.

Professor HALLIBURTON, M.D., F.R.S., reports that during the past year the following researches have been carried out, either by himself or under his supervision, in the Physiological Laboratory, King's College, London: (1) On proteoses and peptone in serous effusions. Recently introduced methods for the detection of these substances have been applied with negative results. A paper by himself and Mr. F. C. Collis has been sent to the *Journal of Pathology and Bacteriology*, and is at present in the press. (2) On the effect of saturating normal urine with certain neutral salts. Magnesium sulphate and ammonium sulphate are much used for the precipitation of proteids. A precipitate so produced in urine, however, is not indicative of the presence of albuminous material, the precipitate produced by ammonium sulphate consisting principally of ammonium urate, and that by magnesium sulphate is inorganic, consisting of calcium sulphate and magnesium phosphate; in the urine of herbivora magnesium carbonate is also present. A paper on the above subject by Mr. A. Edmunds has already been pub-

lished in the *Journal of Physiology*. (3) On creatinine. The experiments of Sir G. Johnson, F.R.S., and Mr. G. S. Johnson on urine have been repeated, and while the general results obtained confirm those of the investigators just quoted, some new points have been made out. Creatinine has also been sought for in the blood by similar methods, and so far the result is a positive one. The investigation has been carried out by Mr. P. C. Collis, who will shortly be in a position to publish his results. (4) On the coagulation of milk. This research, carried out by Mr. Edmunds, is also not completed.

Professor VICTOR HORLEY, F.R.S., and Dr. A. BUTLER HARRIS, have sent the following report on Ehrlich's method of estimating the oxidation changes in living tissues: Since Professor Ehrlich has demonstrated that the intravenous injections of methylene blue afford ready means of estimating the degree to which oxidation or reduction relatively occurs in every living tissue, little use seems to have been made of this valuable method. The authors, believing that this was probably due to the fact that but few records were made of the phenomena relating to normal animals, have carried on during the last two years a large series of experiments, in order to map out the above-mentioned distribution. Such is easily obtained, since the intensity of the blue coloration or the absence of the same depends upon the degree of oxidation or reductions occurring in the tissues. The following is the order of the tissues in which they are found to be coloured just before death (after which, as Ehrlich has shown, reduction takes place):

DEEP BLUE COLORATION.

Parathyroid, thyroid.	Liver.
Heart.	Ovary.
Pancreas.	Intestine.
Kidney.	Testis.
Pyloric end of stomach.	Cardiac end of stomach.
Central nervous system.	Adrenals.
Duodenum.	Cartilage.
Spleen.	Lung.
Jejunum.	

As regards excretion of the methylene blue and the condition of oxidation of the secretory products the following has been observed:

Stomach.—Notable excretion of methylene blue for the most part as such into the cavity of the stomach; the remainder being excreted as a greenish tint, which, by exposure to the air, rapidly oxidised to the normal blue.

Kidneys.—In a perfectly normal animal the kidneys excreted the methylene blue as such, but in due proportion to the degree to which fatty degeneration of the organ had occurred; the urine was altered, the body excreted being of a greenish tint, or in extreme cases of a greenish grey colour. In each instance the urine became blue on exposure to the free oxygen of the air.

Salivary Glands.—After the injection of blue has commenced saliva is freely excreted, but contains no blue or reduced blue until the substance has been introduced in large quantity into the animal; but in proportion as the quantity introduced becomes greater the methylene blue as such is excreted in small quantities by the salivary gland.

Milk.—Methylene compounds are excreted in this secretion in the reduced form; exposure to air rapidly oxidises them to a blue colour.

RELATION OF THE COLOUR TO THE ACTIVE PHYSIOLOGICAL PROCESSES.

As regards the relation of the blue coloration to physiological activity, this can be best seen, as Ehrlich has pointed out, in the brain. They have repeated his experiment many times, and are fully convinced of its accuracy. It consists in the fact that if the cortex be excited with a faradic current while the blue coloration is at its height local reduction occurs in the area stimulated; whereas if the tissue be kept warm and protected at rest recuperation occurs and the blue coloration is reestablished. This process of physiological reduction and reoxidation can be repeated as long as the cortex is excitable, but ceases, as may naturally be expected, as soon as the excitability is lost.

Another good example which they have observed is in the pyloric end of the stomach. In this region the blue coloration is best marked when the digestion is in active progress.

Another case is that afforded by voluntary muscles, in

¹ Kartulis, *Ann. Anat.*, 1890, p. 25.

² L. Pfeiffer, *Presence of Acidoblastic organisms*, pp. 149 and 154.

which the blue coloration indicative of active oxidation appears in a very marked degree in muscles which are kept in a condition of marked activity by evolution of their respective nerves.

RELATION OF THE COLOUR TO ACTIVE PATHOLOGICAL PROCESSES.

The authors commenced the foregoing work with a view to determining the relation of oxidation to fatty degeneration. But this portion of the research is still in progress, and therefore incomplete; nevertheless certain facts have appeared clearly.

As regards the voluntary muscles, if a motor nerve is divided at varying periods before the injection is made the muscle which is analysed shows a more intense coloration after methylene blue has been injected than in the normal condition. This appears to last for some weeks.

As regards the parenchymatous organs, they have repeatedly examined the stages of fatty degeneration on the kidney, and have found that the degree of blue coloration is directly proportional to the stage of degeneration; and further, that this condition commences in two cortical convoluted tubules, and when markedly present the excretion is of the granular type already referred to.

To avoid error of interpretation of the estimation of the colour, the authors have throughout the research employed the method of subcutaneous injection, and not the intravenous method originally introduced by Ehrlich.

Dr. JOHN A. HAYWARD reports that the research in aid of which a grant has been afforded to him has been conducted chiefly with the view of determining the best method of recognizing and cultivating the diphtheria bacillus from membrane, and thus simplifying the early diagnosis of doubtful cases. Thirty cases of suspected diphtheria were examined, and the relative growth of the bacillus on nutrient agar, glycerine agar, gelatine, or serum, horse serum, antitoxic horse serum, and hydrocele fluid was investigated. The latter medium was solidified after fractional sterilisation by heating to a temperature of 60° C. Dr. White has since simplified the process by a modification of Lorrain Smith's treatment in the preparation of ordinary serum. Thus prepared, the hydrocele fluid forms a clear, solid, semitransparent nutrient medium. The bacillus was found to grow more readily on serum and the coagulated hydrocele fluid than on any other medium; the latter presenting the further advantage in that it seems to be inimical to the growth of staphylococcus aureus and albus, and to a certain extent of some of the varieties of streptococci, which are so constantly found in the membrane, and which on other media over-crowd and render difficult the detection and separation of the bacillus. Both on serum and hydrocele fluid the bacillus can be recognised and separated generally within twenty-four hours. The cultures were most readily made by taking a small piece of membrane, washing it thoroughly in saline solution, drying between blotting paper, and then smearing over the surface of the nutrient medium; using the same needle subcultures are made successively on four or five fresh tubes, thus separating and diminishing the number of colonies. This method is both preferable and less troublesome than making plate cultivations. Hydrocele fluid has the disadvantage that it varies in coagulability, and on it, as with other media, the rapidity of the growth of the colonies varies in different cases. Horse serum and antitoxic horse serum, when solidified at a high temperature, were found to form as good nutrient media as ox serum. In fluid antitoxic serum the bacillus remained alive for at least forty-eight hours, as proved by subcultures. At this time many "evolution" forms were observed, but further observation was hindered by contamination of the tubes and lack of material. The serum which had been inoculated with the bacillus, and incubated at 37° C. for forty-eight hours, still retained its antitoxic properties as proved by the protection which it afforded to a guinea-pig inoculated at the same time with a virulent broth culture. Nutrient and glycerine agar are not suitable for early diagnostic purposes, as the overcrowding of other micro-organisms which grow more quickly than the diphtheria bacillus render recognition and separation difficult. In the examination of these thirty cases a particularly striking feature has consisted in the great variability ex-

hibited in the size and shape of the bacillus, and in the relative rapidity of the growth of colonies from different cases. *Cateris paribus*, as might be expected, the colonies grow more readily the earlier in the disease the cultures are made, and when the membrane is being actively formed or renewed. No correspondence could be made out as regards the association of particular varieties of the bacillus with clinical varieties of the disease, and in the majority of cases after cultivation mixed forms were observable. It would appear that any deductions on this point must be made from direct microscopical examination of the bacilli as they occur in the membrane, and not after artificial cultivation. Experiments have also been made to test the relative value of certain so-called solvents of diphtheritic membrane. Small portions were subjected to the action of lime water, bicarbonate of soda (10 grains to the ounce), bicarbonate of potash, Benger's liquor pepticus and pancreatius, lactic acid, papain (Finkler), hydrogen peroxide (30 vols. per cent.). Of these lime water was found the most efficient; small pieces of a tough membrane were dissolved in about 15 minutes, leaving a slight loosely coherent and flocculent residue. Next in solvent power comes liquor pancreatius, a drachm of which with a few grains of bicarbonate of soda dissolved a tough piece of membrane in 20 minutes when kept at a temperature of 39° C. Liquor pepticus, acidulated with hydrochloric acid, was considerably slower in action. The remaining agents were practically without effect on the membrane. A saturated solution of papain (Finkler in glycerine) had no appreciable effect in half an hour. Hydrogen peroxide (30 vols. per cent.) has been strongly recommended from America as a powerful remedial agent for clearing away membrane and destroying the bacillus, especially when the solution is acidulated. As far as experimental results go, it has proved disappointing; it has no distinct solvent effect on membrane, and bacilli grew readily in subcultures from a solution five minutes after they had been introduced. A favourable opportunity occurred for examining the air expired in an early and virulent case of diphtheria. A sterile glass funnel, the sides of which were coated with a thin layer of glycerine, was fitted over the nose and mouth of the patient, and the narrow end of the funnel loosely plugged with cotton wool. Respiration was conducted through this apparatus for ten minutes. Subcultures were immediately made from the glycerine surface, but no colonies of bacilli could be detected by culture or direct examination of the glycerine, but a colony of cocci appeared on one of the agar subcultures. Attempts have also been made to determine something of the life-history of the bacillus diphtherie when grown in sewage which has been previously freed from micro-organisms by either (1) sterilisation or (2) filtration. No definite results have been obtained as yet; the bacilli appear to remain active in the sewage for at least a week. In one instance they ceased to yield subcultures after ammoniacal decomposition of the fluid.

Dr. R. T. HAWLATT reports that his investigations of the chemical nature and constituents of malignant tumours has been continued in several directions. One of the most important results obtained so far is the fact that proteoses (albumoses) seem to be completely absent from carcinoma, sarcoma, and fibro-adenoma. On the other hand, a small amount of a proteose has been obtained from the livers of rabbits suffering from coccidial disease. This substance, however, did not seem to possess any marked physiological action. A report on this part of the subject is practically ready for publication, and will be forwarded shortly. The examination of the proteoses contained in the spleens of carcinoma patients and a comparison of these with the same substances met with in the spleen in other diseases has been continued and will shortly be completed. A micro-chemical investigation of the so-called parasitic protozoa of carcinoma has also been undertaken. The examination of carcinomatous tissues for chitin has so far given negative results. A detailed examination of the proteids of carcinoma and sarcoma has still to be made.

Dr. R. M. HORNE reports that in his investigation he has first of all endeavoured to determine whether an albumose is normally present in muscle. Halliburton has stated that the muscle ferment is of the nature of an albumose. Whitfield, however, whose paper was published after Dr. Horne had

begun this research, was unable to find any evidence of the existence of an albumose in muscle. His own experiments lead him to believe that there is normally in rabbit's muscle a small quantity of an albumose possessing characters which indicate that it is closely related to the dextro-albumose of Kuhn. Dr. Horne has also obtained from rabbit's muscle, by Woodbridge's method, a substance having the properties of a nucleo-albumen. After purification it was found to contain organic phosphorus; it yielded a residue after long-continued digestion in artificial gastric juice, and its solutions produced intravascular coagulation when injected into the blood vascular system of rabbits. Dr. Horne made some experiments to determine the action of solutions of nucleo-albumen, leuco-nuclein and leuco-histatin, upon the coagulation of heated muscle plasma (prepared by extracting rabbit's muscle before rigor mortis had set in, with various saline solutions). The varying results obtained, depending upon variations in the reaction of the media in which the substances were dissolved, do not admit of any conclusions being drawn. The reaction of muscle extracts is one of the most important factors influencing their coagulation. A slight alteration in the reaction towards the alkaline side delays or prevents coagulation; a slight alteration towards the acid side materially hastens coagulation; diyo-albumose hastened coagulation even in a faintly alkaline medium.

Dr. A. A. KANTHACK has sent the following preliminary report on the distribution of the bacterium coli commune. It is either stated or tacitly understood by most observers that the presence of the above organism implies fecal contamination, and water or food has been condemned on that account. The above group of organisms is considered to be a normal inhabitant of the large intestine. For reasons which need not be stated here, these statements assumed not to rest on facts, and if they are incorrect much harm may be done to water companies, food vendors, etc. It was found that the bacterium coli group is as widely distributed as the bacillus fluorescens liquefaciens group. The latter also is found in the intestines, and we have therefore no right to assume that fluids or substances containing a bacterium coli, even in abundance, have been contaminated with or from fecal matter. The bacterium coli organisms were found plentifully in (a) sputum, whether pneumonic, bronchitic, influenzal, tuberculous, or normal; (b) in saliva very frequently; (c) in many diphtheritic membranes; (d) in various suppurating wounds; (e) in all cases of gangrene, cancerum oris, phagedena; (f) in cases of angina Ludovici; (g) post mortem in the lungs of almost all individuals; (h) in the secretion from the cervix uteri; (i) often in the urine that had stood for twelve hours; (k) often also in cystitic urine; (l) dust was hardly ever free from them; nor (m) sand or earth, or (n) water exposed to the air; (o) frozen mutton was also inhabited by them; and (p) they were found also in the snow crystals of the freezing chambers. It is seen then that these organisms are not merely restricted to faeces, but are ubiquitous, and that, therefore, we have no right to conclude that their presence means fecal contamination. Dr. Kanthack is continuing the research as to the variability and pathogenic properties of these organisms, their neophological and biological characters. So far his criticism is directed against the fecal contamination theory and its obvious fallacies.

Dr. W. S. LAZARUS BARLOW and Mr. G. E. PHILLIPS have been engaged during the past year in an investigation into the oedema of inflammation. The results are not yet in a sufficiently advanced condition for full publication, but it may be stated that so far they have found that there is a marked difference between the specific gravity of the muscles immediately beneath a blister, those underlying the edge of the blister, and those at a distance from it. If these muscles be compared with those on the uninfected side, it is found that the muscles immediately beneath the blister are considerably lower in specific gravity, and those beneath the edge of the blister are somewhat lower in specific gravity. The fact might have been suspected, but the interesting point shows itself with regard to the muscles at some distance from the blistered area. Here there is a considerable rise in specific gravity as compared with the uninfected side. It appears, therefore, that fluid is abstracted from the regions around an inflamed spot to supply fluid immediately beneath that spot. Other investigations carried out by aid of the

grant from the British Medical Association have already been published and acknowledged by one of them (W. S. B.). In a paper on the Pathology of Oedema, published in the Journal on March 23rd and 30th of the present year. The research is still being carried on. The investigation into the action of the diphtheria toxin upon the heart has not made a great progress during the year, chiefly because of the amount of time consumed in the isolation and preparation of the toxin. This, however, has been prepared in some quantity in the dry state, and has been compared in its action upon the living animal with albumose prepared by the kindness of Dr. Sidney Martin. The experiments show that there is no essential difference between the action of the filtrate from diphtheria cultures and of the purified albumose, excepting of course in the amount to be injected. Future experiments, therefore, will be carried out with the filtrate, and consequently it is to be expected that the work will progress more rapidly.

Dr. MORE has been engaged in an experimental inquiry upon the afferent tracts of the central nervous system of the monkey. Results of fourteen experiments (for full details of which see *Brain*, vol. i, p. 1, 1895). The column of Goll is formed especially by fibres entering by the fifth, sixth, and seventh subthoracic roots. After unidirectional unilateral section, even of a large number of roots, there is no degeneration in the opposite posterior column. The limit of Goll ends in the nucleus of the funiculus gracilis. When this nucleus is destroyed or the fibres issuing from it separated from the cells of the nucleus, a degeneration occurs in the internal arciform fibres, the opposite interolivary layer, and fillet, which can be traced up to the optic thalamus. It is impossible to injure Goll's nucleus without the nucleus being involved, and he finds experimentally that the greater number of fibres of the fillet come from the latter nucleus. In no case could degenerated fibres be traced to the center. Thus there is no experimental evidence in favour of the existence of a cortical fillet direct from the posterior column nuclei. Unilateral section of lumbosacral roots is followed by degeneration of a variable number of fibres in both antero-lateral regions. A similar degeneration, but much more extensive in this region, occurs after median section in the upper lumbar region. In the paper mentioned Dr. More points out the fact that the antero-lateral tract of Gowers probably consists of fibres arising from cells of the grey matter of the opposite side, and that they are of two sets, having different destinations: (1) The more numerous are cerebellar, which cross in the anterior commissure, and, after looping over the fifth nerve, run on the posterior surface of the superior cerebellar peduncle, to reach the middle lobe of the cerebellum. (2) Another set of afferent fibres, which also cross in the anterior commissure to form probably the crossed afferent tract of Gowers and Edinger, the function of which is unknown. This tract can be traced up the cord, the nucleus, the pons, terminating in the corpora quadrigemina. The lesions and the resulting degeneration are all illustrated by photomicrographs. The method of staining adopted has been the Marchi method, which, properly controlled, is by far the best for tracing early degenerations.

Dr. ROBERT METZ reports that during the past year he has prosecuted an experimental research on leucocytosis, for which he obtained a grant, and in which he is still engaged. He states that the earlier part of the work was beset with many difficulties and fallacies, but now the progress is more satisfactory; many results are ready for publication, and he hopes to continue the research during the next year.

Dr. G. R. MURRAY has returned his grant. Dr. M. S. PERRY reports that the relation of muscular activity to the maintenance of a constant temperature can be studied by testing the response of an animal to changes of external temperature under conditions in which the control of the animal over its muscular system is varied. The response of the normal animal is compared with that exhibited by the animal under anaesthesia, or after section of its spinal cord. The investigation differs chiefly from that of other observers in the shortness of the comparative periods in which the respiratory exchange was determined. Thus it is possible to follow the immediate effect of changes of temperature. The results show that a mouse whose spinal cord has been divided only responds in a manner similar to that of a

cold-blooded animal when it is no longer able, by the activity of the few muscles over which it still has control, to keep up the temperature of its tissues. The relationship of muscular activity to the regulation of heat production is even better shown by the result obtained on anaesthetized mice. A preliminary account on this research was given before the Physiological Society on February 16th, 1895. A full account will probably be published shortly.

Dr. D. W. SAMWAYS reports that in his research, of which he has already sent full particulars, he has endeavored to show that the diastolic wave of the pulse is in all probability not produced by reflection at the aortic valves or in other ways commonly suggested as possible, but rather is consequent on the shortening of the first part of the aorta when the ventricle relaxes. The fact of the elongation and straightening of the ascending aorta during the cardiac systole is well known, but he has never seen discussed the pressure changes which occur within the aorta on its longitudinal recoil after the systole is over. He has shown in his experiments that the diastolic wave of the pulse and natural pulse tracings may be perfectly imitated by employing a pump and an elastic system of tubes to represent the circulation in the ordinary class-room manner. It is necessary only while working the pump to stretch the portion of tube adjacent to it during the systole and release it during the diastole, thus mechanically imitating the natural circulation. The superposition of the diastolic rise on the descending limb of the main pulse wave is then very evident. Dr. Samways shows also that in the dog, if the longitudinal movement of the first part of the aorta be prevented by fixing it near the heart the diastolic wave at once disappears. He regards, therefore, the diastolic wave as chiefly, perhaps entirely, due to the "ballistic action" of the aorta recoiling longitudinally on the blood column. This raises the blood pressure locally and starts a wave, which may be easily shown to be greater when the recoil is more rapid, that is when the liquid pressure is less. The longitudinal recoil commences somewhat later than the circular, upon which latter the transmission of the main pulse wave along the arteries depends. At the end of his paper Dr. Samways has suggested that it is this longitudinal recoil of the aorta which, pushing on the base of the ventricle like a receding piston, tends to open up its cavity and is the probable mechanical cause of the negative pressure often observed in the ventricle at the commencement of its diastole. Lack of time has prevented his completing his experiments, but he hopes to confirm and extend them at an early opportunity.

Dr. THEODORE SHENMAN reports that since his last report he has obtained a fair quantity of catha leaves. These, when examined microscopically, show few peculiarities which are out of the way. The upper surface shows the ordinary network of cells. The lower, in addition, shows stomata, with well-marked guard cells and groups of crystal-containing cells. Under the epidermis there are two rows of palisade cells, of which the lower has the less number. Dr. Shennan has obtained an alkaloid in small quantity which is not caffeine; also tannic acid, glucose, a resin in small quantity, and chlorophyll. The leaf as obtained here contains 5.52 per cent. of moisture. The alkaloid (impure) was got as a fawn-coloured syrupy liquid. This, when dissolved in absolute alcohol and filtered into ether, falls as a white flocculent precipitate, which in time forms a viscous layer on the bottom of the beaker. It gives precipitates with phosphomolybdic acid, phosphotungstic acid, picric acid, solution of iodine in potash, iodine solution. No precipitate with tannic acid in neutral, acid, or alkaline solutions; light-green coloration with strong sulphuric acid plus potassium bichromate. No change with Fehling's solution. It is non-volatile. If a neutral solution of it be instilled into the conjunctival sac of a rabbit, it dilates the pupil. If the impure alkaloid, as obtained by precipitation of an alcoholic strong extract by ether, be injected into the common rat, hypodermically or intraperitoneally, it causes death with tetanic convulsions, easily induced, in from four and a-half to twenty-eight hours—that is, with a dose varying from 0.007 gramme to 0.063 gramme per gramme of body weight. *Post mortem* the heart was in diastole. The first indication of action in these animals was an opacity of the cornea, after which a staggering gait was noticed. In frogs, if a large dose be given, coma and death supervene; if smaller, after a time reflexes, particularly the

abdominal, are increased and at last tetanic spasm can be induced very readily. *Post mortem*, ventricles generally in systole. Such results are very closely allied to those got with caffeine, and argue the presence of that active principle. So far, however, no one has been able to isolate it from catha. Dr. Shennan is now engaged in trying the various methods of extracting caffeine from tea, and applying them to catha, in order to afford a check, and make sure that the absence of caffeine is not due to faulty methods of extraction.

Dr. H. R. SMITH reports that he has been enabled to make a complete chemical examination of 24 different pathological fluids, including 6 ovarian tumours, 2 parovarian, 8 cases of ascites, 3 pleuritic effusions, 2 hydroceles, 1 oedema fluid, 1 dermoid fluid, and the contents from 1 pancreatic cyst. In every case he has estimated the specific gravity by means of the pycnometer; the total solids, water, and ash have also been determined. The total quantity of albumen has been estimated by weight after precipitation with absolute alcohol; it has also been estimated by Esbach's method in order to form some definite idea of the accuracy of this latter method; the presence or not of pseudomucin and nucleo-albumin has been determined and the total quantity of nitrogen has been estimated by Kjeldahl's method, and this compared with the total albumin to determine if it were all accounted for by proteids, or whether some were due to extractives; the total alcoholic extract and ether extracts (so-called fats) were estimated, and in the latter the percentage of cholesterolin, leucithin, and fat acids have been determined. The result, show conclusively that the chemical analysis of pathological fluids is not to be relied upon for assisting in the diagnosis as to the origin of the fluid, with the exception that fluids of inflammatory origin contain more albumin than simple effusions. In no instance was any single constituent or group of constituents present in such a form or quantity as to enable one to form any reliable idea as to the origin of the fluid. One interesting fact brought out in these researches is that the presence of pseudomucin is by no means pathognomonic of ovarian fluid, as was once imagined. Dr. Smith detected its presence in the following fluids, in addition to ovarian and parovarian fluids, in ascites of varying origin, in one case of pleurisy, in one of hydrocele, and in dermoid secretion. The total salts in all the fluids were exceedingly constant, varying only from 0.54 per cent. to 0.82 per cent. The percentage of cholesterolin, leucithin, and fats varied very greatly, and this variation bore little or no relation to the nature of the fluid.

Dr. W. L. SYMES reports that during the past twelve months his work on nerve sections has been in abeyance, and attention has been given to certain crystals that form in strong solutions of alkalate albumin. Lieberkuhn's jelly (soda), in the course of a few hours or days, liquefies, and if exposed to the air the fluid develops a large crop of colourless rhombic or monoclinic crystals, which are freely soluble in distilled water, and which on drying tend to become efflorescent. They are strongly alkaline, and consist largely of sodic carbonate. Prolonged washing fails to free them from proteid, as evidenced by the precipitability of their aqueous solution, by picric, trichloroacetic, and salicyl-sulphonic acids; and its colour reactions with the xantho-proteid, and (after elimination of CO₂) Piobrowski's reactions. They are now under quantitative analysis.

Dr. A. H. TUNNY reports that experiments have been carried out by him with reference to the following points: (1) The immediate and more remote effects of opening the pleural cavity on blood pressure. (2) The effect of the injection of various fluids in the pleural cavity, the fluids being such as are in ordinary surgical use. (3) The possibility of transference of solid particles suspended in saline solution from the peritoneum to the pleural cavities. With reference to No. 1: In six experiments the effect of opening one pleural cavity—say the right, for example—in cats is to cause a somewhat sudden fall of blood pressure, varying from 10 mm. to 18 mm. of mercury, and lasting for one and a-half to two minutes. Blood pressure then rises again nearly to the normal. In some cases it happens that the two pleural cavities in the cat communicate, and the opening of one is followed by a condition of pneumothorax on both sides of the chest. When, however, the pleural sacs are duly separated, on sucking out the air which has been let into

one of them the normal pressure is immediately restored. No. 2. The fluids which have been injected into the pleural cavity are three, namely, carbolic acid solution, 1 in 40; tincture of iodine solution, 1 in 60; and perchloride of mercury, 1 in 3,000. The effects of injection of 30 c.cm. of carbolic acid solution, 1 in 40, are very consistent. There was an immediate fall of blood pressure, varying from 12 mm. to 25 mm. of mercury, accompanied by inspiratory convulsions and great irregularity of the heart, death ensuing in from two to three minutes. In one instance, the carbolic acid having been injected into the right pleural cavity, the lung was found to be intensely red, while in the left pleural cavity there was some fluid, coagulable on heating. In another case, whereas 30 c.cm. of carbolic acid solution were injected into the right pleural cavity, causing death in four minutes and a half, 50 c.cm. were found on making an immediate *post mortem* examination. The effects of putting in 30 c.cm. of 1 in 160 iodine solution were very slight. A temporary fall of blood pressure occurred, followed by a subsequent rise, accompanied by irregularity of the heart, but beyond that no ill effects seem to have been felt. The effects of injection of the solution of 1 in 3,000 perchloride of mercury were at variance, and it is intended to make some more experiments with this substance. If 60 c.cm. of normal saline solution be put into one pleural cavity, and the animal be kept alive for four days and examined afterwards, it will be found that no trace of the fluid remains in the cavity. No. 3. The possibility of the transference of solid particles suspended in saline solution from the peritoneum to the pleural cavities: 50 c.cm. of 1 per cent. Berlin blue solution in 0.75 sodium chloride solution were put into the peritoneal cavity, and into the right pleural cavity 50 c.cm. of saturated salt solution were put. In one hour, on removing the fluid from the pleural cavity and centrifugalising it, no signs of any blue particles were found in it. If, instead of placing saturated saline solution, normal saline solution were placed in one pleural cavity, the Berlin blue being in the peritoneal cavity as before, and artificial respiration be kept up for one hour, again no trace of Berlin blue is found in the fluid recovered from the pleural cavity. But to make these experiments of value, they should be conducted for from six to twelve hours. However, it would seem from some experiments by Dr. Starling and Dr. Tabby detailed in vol. xvi of the *Journal of Physiology* that lymphatics play but a very subordinate part in the entrance to and exit from the pleural cavity, even of soluble methylene blue dissolved in normal saline solution.

Dr. SWALE VINCENT reports that his work is by no means complete, but he has a paper ready for publication which embodies the work as far as it has progressed. He has endeavoured to make the investigation a contribution to the comparative anatomy and histology of the suprarenal capsules, and for this purpose he has investigated these bodies in certain orders of fishes, namely, in Elasmobranchii, Ganoidae and Teleostei, and to some extent also in the Dipnoi. He has examined in all fifty types, including representatives from the above named orders. The Cyclostomi are not included. He has noted in each species examined the exact anatomical relations of the suprarenal bodies, and in the case of the Elasmobranchii their relation to the sympathetic nervous system. He has also made careful histological preparations of the suprarenal of all the types examined, employing very various modes of hardening, staining, and preparing. As a general result, he has come to the conclusion that the suprarenal capsules in fishes are secreting glands just as those of mammals are now supposed to be, that is, that these bodies manufacture and pour into the blood some material which is essential for that fluid. They are therefore in a true sense "blood-vascular glands."

Dr. J. C. WENSTEN reports that during the past year he has carried on his work with reference to the determination of the question of wandering of the ovum, external and internal; the other parts of his research he has not been able to continue in consequence of the severity of last winter; he is returning his grant, and applying for a renewal.

Dr. A. H. WHITE has been engaged in a research on the effects of repeated hemorrhage on the composition of the blood, and reports that the subject is of such an extensive

nature and the amount of work entailed in its thorough investigation so great that, notwithstanding the very large number of analyses already made its outskirts only have been touched. Large dogs were employed, and so far as possible it was endeavoured to have the conditions under which the bleedings were performed identical. Estimates and analyses of the first portion of blood lost were made, of the number of corpuscles and percentage of haemoglobin, of the time it took to coagulate, its specific gravity, the amount of water and solids, total proteins, fibrin, ash, and ether extract; while in addition about a dozen cover-slip preparations of the blood were made, fixed, and put aside for subsequent staining and examination. Up to the present nine dogs in all were used, but from two of these no results were obtained, the animals dying a few hours after the first bleedings (4.4 per cent. and 4.5 per cent. of body weight respectively lost). Appended is a table giving the full result of the analyses, etc., in the case of the dog.

Weight.—The animals were in all cases carefully weighed before being bled, and the total amount of blood lost at each bleeding was carefully estimated. In consequence of the bleedings the animals lost weight, but not in proportion to the quantity of blood withdrawn.

Quantity of Blood Lost.—The amount of blood taken away at a single successful bleeding varied from 0.8 per cent. to 4.2 per cent. of body weight. Cohnheim says animals often do not recover after the loss of 3 per cent. of body weight, and further, that when the quantity of blood lost equals 3.5 per cent. to 4 per cent. the animal is seized with convulsions and dies. In these experiments no dog died from the loss at first bleeding of less than 4.4 per cent. of body weight, and one dog lived in spite of a loss of 4.2 per cent. Of course a much greater quantity of blood may be lost when spread over a few days, as, for example, one dog in three days lost 5.3 per cent. of original body weight, or about five-sevenths of the original quantity of blood.

Specific Gravity.—The specific gravity was, as a matter of course, always lowered, but never seemed to fall so much below normal as it does in bad cases of chronic anemia and chlorosis. This fall in the specific gravity bore no constant relationship to either the corpuscles or haemoglobin; these does, however, seem to be some relationship between the amount of its fall and that of the proteins.

Water and Solids.—The disturbance between the relative proportions of the water and solids is well marked.

Total Proteids.—The quantity of total proteids is greatly diminished, but not in proportion to the amount of blood lost; for example, the loss of 38 per cent. of total blood in two bleedings reduced the proteids to only 89.3 per cent. of original amount.

Fibrin.—After each successive hemorrhage the increase in the amount of fibrin is steady and striking. For example:

	Blood Lost (Per cent. of Body Weight).	Fibrin in 100 parts of serum.
Normal blood	0.0	0.0
Twenty-four hours after 1st bleeding	1.1	0.1
" " 2nd "	0.8	0.2
" " 3rd "	0.8	0.2

(See also table at end.)

Ash.—The amount of ash, contrary perhaps to general opinion, was markedly diminished as a result of the bleedings.

Ether Extract.—The ether extract would seem to be increased, but many further analyses and by different methods must be made.

Coagulation Time.—As regards the time which the blood takes to coagulate, it appears to be wholly unaffected by the amount of blood lost; and also the amount of ash, there is no relation to the rapidity or slowness of the act of coagulation. There appears to be, however, some connection between the coagulation time and the quantity of ash, but at present it would be unsafe to push the connection too far.

Haemoglobin.—The fall in the proportion of haemoglobin at the end of twenty-four hours is exactly proportional to amount of blood lost. Its restoration to the blood seems to begin between twenty-four and forty-eight hours after the bleeding.

Formed Elements.—A full examination of the formed elements has not yet been made. The red corpuscles, however,

greatly diminished, though not in proportion to the amount of blood lost; there is little or no change as regards their size and shape. In a few cases the increase in the haematocrit was quite striking. The *schistocytes* are increased, indeed, in some instances the leucocytosis is quite marked in the later days of bleeding, in which cases almost, if not more than, 50 per cent. of the corpuscles are of the polynuclear variety.

The experiments were carried out in the Chemical Pathology Department of the University College, London, under the kind direction of Dr. Vaughan Harley.

Dr. HALE WHITT has, in conjunction with Mr. F. G. HORSKING, continued his work in connection with animal calorimetry. During the winter much has been done to improve the accuracy of working of the instrument.

RESEARCH SCHOLARSHIP.

Dr. W. SOLTAN FENWICK has sent the following report, which is a short abstract of a paper which was published in the *JOURNAL* of April 13th last, in conjunction with Mr. BOKENHAM, entitled, *Some Researches into the Chemistry of Typhoid Fever*. The spleens obtained from four cases which had succumbed to enteric fever during the third week of the disease were removed from the body as soon as possible after death, and submitted to the same chemical process which they had formerly employed in their researches upon septicæmia. In this manner three varieties of organic extracts were obtained: (1) A material which was insoluble in absolute alcohol, but freely soluble in water, and which afforded all the chemical reactions of an albumose. (2) A substance which was extremely soluble both in water and in absolute alcohol, and possessed most of the characteristic features of an alkaloid. (3) A dark coloured, semi-solid material consisting of a mixture of fat and fatty acids. The pathological effects of the different substances were next tested by injection into rabbits, guinea-pigs, and rats. 1. The Albumose. This was administered in doses ranging from 0.02-0.8 gramme per kilo of the body weight. In all cases both the subcutaneous and intra-venous injection was followed after an interval of four or five hours by severe pyrexia, thirty hours or more elapsing before the temperature regained the normal point. During this period the animals lost appetite and weight, but death never occurred, even when large and repeated doses were given. The animals were killed at varying intervals after the injection, and the tissues of the body submitted to microscopical examination. With the exception, however, of some degree of cloudy swelling in the renal epithelium, no evidence of disease was forthcoming. These results present a marked contrast to those obtained by Martin in cases of diphtheria, and by Dr. Fenwick and Mr. Bokenham in scarletina. 2. The Alkaloid. This extract was employed in doses varying from 0.03-0.5 gramme per kilo. No phenomena of interest followed the injection of this substance, nor did the various tissues after death present any signs of disease. 3. The Fatty Extract. This was liquefied by the action of heat, and administered subcutaneously. Its only effect was to cause a temporary fall in the temperature of the body, but neither fever nor temporary lesions followed its repeated injection. During the past four months Dr. Fenwick has been occupied with an investigation into the etiology

and pathology of the marasmus of infants, which he hopes to have ready for publication by the end of next October. The following are some of the facts which have been ascertained up to the present time: 1. The stomach, intestines, liver, and spleen derived from 10 fatal cases of marasmus were submitted to careful microscopical examination. In every instance the stomach was found to be the seat of a chronic form of gastritis, which commenced as a round-cell infiltration in the interstitial portions of the mucous membrane, and finally gave rise to complete cirrhosis of the organ. The duodenum, small intestine, and colon were affected in a similar manner, but parenchymatous inflammation often co-existed with the interstitial form. In most cases the liver was found to be in a state of fatty degeneration, and the kidney exhibited signs of parenchymatous inflammation. 2. Bacteriological examination of the diarrhoea resulted in the isolation of numerous varieties of micro-organisms, each of which has been separated and cultivated in a pure state. Experiments have been performed with the pure cultures in order to discover the pathological and clinical phenomena which result from the inoculation into inferior animals. Finally, the toxins of the principal varieties have been manufactured and their action upon animals investigated. The various micro-organisms have been grown upon media containing definite proportions of antiseptic substances, and the results compared with those obtained from the internal administration of the same drugs to children suffering from diarrhoea and marasmus. This portion of the subject will be embodied in a contribution to the Therapeutic Section at the annual meeting. Exhaustive investigations have also been made into the secretion of the gastric juice in similar cases, and the compositions of the excreta have been studied with a view of determining the cause of the hyperacidity of the faeces which usually exists.

Dr. E. LLOYD JONES reports that during the past year he has continued his observations on the blood in healthy persons, measuring the specific gravity of the whole blood, and as often as possible the proportion of corpuscles to serum, the quantity of hæmoglobin, and the specific gravity of the serum. He has also kept records of cases of chlorosis. These observations show that the blood of the female before puberty resembles the blood of the male, but at about 16 years of age the quantity of hæmoglobin becomes diminished, the specific gravity of the blood becomes less, the red corpuscles become relatively fewer. In many women there is a slight change in the same direction at each menstrual period. The blood varies in different types of healthy persons: thus persons with light eyes, hair, and complexion have lighter blood than darker persons. These differences bear a curious relation to the fertility of the mother. Thus in the case of a number of healthy males the relation between the specific gravity of the blood and the number of brothers and sisters was as follows:

1000	5 to 9
1007	5 to 7
1008	5 to 6
1009	4 to 5

Showing that the males whose blood most nearly approached the female kind of blood, had many brothers and sisters. He

is not yet provided with a sufficient number of observations on suitable females. In chlorosis the blood exhibits: (1) Marked diminution of the hæmoglobin, (2) diminution of the specific gravity, (3) a diminution of the volume of red corpuscles. Among the signs of chlorosis bearing most on its pathogeny are probably dilatation of the heart, rapidity of the pulse, gastropnoia, a tendency to gastric pain, gastric and intestinal congestion and hæmatemesis, with or without the occurrence of ulceration; slight but evident enlargement of the thyroid, and weakening of certain voluntary muscles. Chlorotics are most prone to relapse at or about their menstrual periods. Some experiments reported by Dr. Jones the year before last show that after section of the splanchnic nerves or destruction of the spinal cord high up in the neck, the injection of saline solution leads to a more permanent lowering of the specific gravity of the blood than is usually the case, while there is very marked gastro-intestinal congestion and even hæmatemesis. Recognising some analogies between Graves's disease and chlorosis, he sought for some source of auto-intoxication on the latter disease. So far his experiments with ovarian, Fallopian, and uterine tissue have given negative results. The combined administration of Fallopian tissue with common salt, however, produced a marked diminution of the percentage of hæmoglobin, and in this relation it may be added that he found the blood of chlorotic women to be more alkaline than that of healthy women. Before the August meeting he will have investigated the action of salt given alone. If salt alone will produce this effect we have a means, possibly, of treating those persons (of whom he has written in other reports) who are pale, but who have an excessive proportion of red corpuscles. In conclusion, the blood of chlorotics presents in an exaggerated degree the characters shown by the blood of those healthy persons whose mothers were most prolific. Of this he was aware last year, and reported so to the Scientific Grants Committee, but only during this year has he found that in all persons of unmixed race one can tell the fertility of the mother from an examination of the blood of the children. With regard to the treatment of chlorosis, the most successful prophylactic measures appear to be a plentiful flesh diet, combined with a due amount of exercise. Among drugs, no one appears to be capable of replacing iron in the treatment of chlorosis. No form of iron does better than the reduced metal, the carbonate or the hydrate. Some of the newer preparations—for example, ferratin, hæmogallol—sometimes acted well, but, like all the others, failed in certain cases. Dr. Jones proposes during this year to continue his observations upon healthy persons, to obtain, as far as may be possible, exact figures showing the relation between the composition of the blood and fertility, to determine if possible the relation between the blood of the parents and that of the children, and to continue his observations on chlorotic women with the object of determining the cause of the disease, and particularly whether it be due to an auto-intoxication of any kind.

Dr. G. E. CARTWRIGHT Wood reports that the object of his research was to investigate one of the acute exanthemata, in order if possible to recognise and separate out its specific organism. The first and chief difficulty which confronted him was the fact that the lower animals appeared to be insusceptible or to be practically refractory to these diseases, which rendered not merely the recognition of the parasite—even when separated out—very difficult, but also deprived one of the most efficient means of obtaining fresh and "clean" material for experimental purposes. In consideration of these facts he selected variola and in probably modified form, vaccinia, as the object of investigation, inasmuch as the latter at any rate can be inoculated on certain animals. Unfortunately the animals which are specially suitable for its inoculation—for example, the calf—are not such as can be used for general laboratory work. Dr. Wood obtained several samples of vaccine matter from different sources, and investigated chiefly from the bacteriological point of view, in order if possible to eliminate those from the experiment. The material which he has been able to get has, however, been so very unsatisfactory, from its evident gross contamination from the bacteriological point of view, that it was evident that no advance could be made until the production of the vaccine material could be carried on directly under his own eye as in

ordinary laboratory experiments. Dr. Wood has been engaged accordingly for some time in experiments for the purpose of ascertaining if he could not render the ordinary laboratory animals, such as guinea-pigs and rabbits, susceptible to vaccinia by placing them under certain special conditions. That such a method could be devised was very probable, since it has been known for a long time that one can render the infection much more rapid and fatal than usual by subjecting them to special conditions, and may sometimes even produce such profound constitutional changes in an animal that even ordinary harmless saprophytes can invade the animal body and produce fatal results. He has already obtained certain results in the case of rabbits, which render him very hopeful that this method may be of great service. Dr. Wood also refers to the fact that he has obtained a somewhat similar result with gonococcus material on rabbits, which are naturally absolutely refractory to such material under normal conditions. When, however, the animal has been treated in a special manner, a purulent discharge makes its appearance in the course of the next few days, and continues for several weeks. In this material pus organisms and also gonococci appear to be present, but he has not yet had an opportunity of carrying out the experiments with a pure culture of gonococcus.

J. WARD COUSINS, M.D., *Chairman.*

REPORT OF COMMITTEE ON LEGISLATION FOR INEBRIATES.

ABOUT the beginning of the present session of Parliament your Committee presented a memorial to the Home Secretary, expressing their regret that Mr. Asquith had been unable to introduce the measure which he had announced his intention to present to Parliament, during the preceding session. The Committee reaffirmed their suggested amendments on existing legislation, especially as to removal of the present hindrances to the prompt reception of habitual drunkards in retreats licensed under the Inebriates Acts, as to compulsory curative detention, and as to provision for the poor at the public charge, with the inclusion of excessive indulgence in morphine, and other drugs besides alcohol. The Committee also expressed a hope that the Home Secretary would be enabled to carry out his intention during the present session. The Cabinet and Mr. Asquith have since redeemed their promise by the introduction of a Bill in the House of Lords by the Lord Chancellor on May 21st, when the first reading was passed.

The Government in their Bill has adopted the principal amendments which were put before Mr. Asquith by the joint deputation from your Committee, the Society for the Study of Inebriety, and the Homes for Inebriates Association: (1) Compulsory curative seclusion of the habitual drunkard is to be secured by an order of the County Court of the district where the alleged inebriate resides (subject to an appeal to the High Court) or of the High Court itself, on application by a relative or friend and evidence on oath. (2) The poor are provided for by county councils being empowered to establish and maintain retreats. (3) The term habitual drunkenness is to include the excessive use of opium or any other drug. (4) Appearance of voluntary applicants for admission to a retreat is to be before one justice instead of two justices as at present. (5) Inebriate offenders may, at the discretion of a judge or magistrate, be awarded a term of curative detention in a reformatory in place of incarceration in a prison.

The report of the Scottish Departmental Committee on Habitual Offenders, Inebriates, etc., of which two of your members—Sir Charles Cameron, Bart., M.D., M.P., Chairman, and Dr. Farquharson, M.P.—were members, has recently been issued. The inquiry was most thorough, largely through the indefatigable labour of the Secretary—Dr. J. F. Sutherland; 161 witnesses were examined, among whom were judges, sheriffs, provosts, prison reformers, school and asylum officials, a convict, and an ex-convict. The evidence of physicians and medical experts was also taken, among whom were your Chairman, Sir James Crickton Browne, Professor Gairdner, Dr. Alex. Puddle, Dr. Clouston, and Dr. Hoffman, Inspector of Retreats. The recommendations of this Committee practically embody most of the proposals which have for many years been urged by your

Committee in concert with the Society for the Study of Inebriety. The police court inebriate "repeater" is provided for by proposed labour settlements, to which he would, at magisterial option, be committed for curative purposes. The additional powers suggested would provide for the compulsory therapeutic exclusion of the habitual drunkard as defined by the 1872 Act, at the instance of his or her friends, if these could support him or her; and at that of the Procurator Fiscal, at the public cost, if the inebriate were a public nuisance. Though this procedure is not so satisfactory as would be the much more costly establishment *de novo* of State or municipal special retreats, your Committee is of opinion that the Departmental Committee is justified in affirming that their suggested plan "meets the case of every habitual inebriate."

Your Committee has accordingly resolved to memorialise the Scottish Secretary of State to introduce legislation on the lines proposed by the Scottish Departmental Committee.

The failure of the existing penal treatment of inebriate offenders as a reformatory or a deterrent from drunkenness has been clearly enunciated by the late Departmental Committee on Prisons from a prison point of view. In their report this Committee state that, while it is recognised that habitual drunkards are not criminals in the ordinary sense and should stand by themselves in a special category, the physical craving for drink is a disease which requires medical treatment not at present provided; that this class of prisoners should be dealt with as patients rather than as criminals.

These conclusions of three Departmental Committees within two years, which conclusions were arrived at by the Parliamentary Committee of 1872, have just been confirmed by the Canadian Royal Commission on Intoxicants. Their report condemns the sending of habitual drunkards to prison as neither elevating nor deterring, and approves of the establishment of places to which these persons could be committed for such time as might be deemed desirable, to be subjected during such period of detention to fitting treatment calculated to lead to their reformation.

The Committee recommends its re-election as follows: The President and President-elect, *ex-officio*: the President of Council, Mr. D. B. Balding, J.P.; Mr. R. Welsh Branthwaite, Dr. T. Bridgewater, J.P.; Sir Charles Cameron, Bart., M.D., M.P.; Dr. G. B. Clark, M.P.; Dr. C. R. Drysdale, Mr. George Easton, Dr. J. W. Eastwood, J.P.; Dr. R. Farquharson, M.P.; Dr. W. T. Gairdner, F.R.S.; Dr. W. C. Garman, Dr. J. Hill Gibson, Dr. A. Grant, Mr. F. J. Gray, Dr. C. J. Hare, Dr. Arthur Jamieson, Mr. H. R. Ker, Dr. Norman Kerr, Dr. Longhurst, Mr. R. H. B. Nicholson, Surgeon-Major G. K. Poole, M.D.; Brigade-Surgeon R. Pringle, M.D.; Fleet-Surgeon George Robertson, M.D.; Dr. James Stewart, Clifton; Dr. George Danford Thomas, coroner; Dr. Wynn Westcott, coroner; and Dr. H. W. Williams.

NORMAN KERR, M.D., *Chairman*.

REPORT OF MEDICAL CHARITIES COMMITTEE.

THE Medical Charities Committee has been carrying on the work of investigating the abuse of medical charities in the metropolis during the past five years, and is now extending its action to the provinces. Communications have been made with the various Branches of the Association, asking them to take the matter up and report upon any abuse of charities in their locality, and from many of these centres replies have been received; but as the Branches have only recently been communicated with, many of them have not yet had time to reply. The Committee therefore desire to continue their labours during the following year. Amongst those from whom the Committee have had replies is one from the Birmingham and Midland Counties Branch, where a very extensive inquiry has been held and valuable results arrived at. It was a meeting convened by the Mayor, at which about fifty were present, consisting equally of laymen interested in hospital management and representative medical men chosen at a meeting of the profession some days previously. The following recommendations were made at the termination of the report:

1. The formation of a General Council representative of all the public medical institutions of the city.
2. The formation of an inquiry agency to investigate the circumstances of applicants for treatment at the hospitals.
3. That, apart from first aid and urgent cases, regulations should be framed by the hospitals to exclude trivial cases, and cases where either the patients are in a position to pay for such treatment as they may require, or which could be more properly dealt with under the Poor Law.
4. That facilities should be given for cases so excluded being dealt with by dispensaries or provident associations.
5. That any person recommended by an approved provident association or by a qualified medical practitioner should, as a rule, be admitted to the out-patient departments of the hospitals without further formality.

Other replies received are as follows:

BATH AND BRISTOL BRANCH.—Have appointed a committee to investigate the subject, and have come to the conclusion that abuse does exist in Bristol, and trust to be able to report upon some remedies which they hope may be carried out.

BORDER COUNTIES BRANCH.—The Secretary was directed to write to members resident in places where hospitals existed for their opinion. Members from Hawick and Galashiels reported that no abuse existed in their districts.

DUNDEE BRANCH.—That as the difficulties referred to do not exist in our local medical charities, the adoption of the Committee's recommendations is unnecessary.

EAST YORK AND NORTH LINCOLN BRANCH.—The Hon. Sec. writes: "I am desired to inform you that at present no inquiry as to the abuse of hospitals is deemed necessary in Hull."

EDINBURGH BRANCH.—Resolved: That the Edinburgh Branch of the British Medical Association, while sympathising with the recommendations of the Report of the Committee on Medical Charities, is of opinion that the details of the same are not applicable to this district.

LONDONDERRY AND NORTH-WEST OF IRELAND BRANCH.—The only hospital in the district is the County Infirmary. There is no out-patient department attached to it except for the treatment of accidents. No medicine or advice is given to out-patients. The dispensaries in the town are under the Poor-law and regulated by Act of Parliament.

NORTH OF IRELAND BRANCH.—Resolved: That this meeting, having heard the statements regarding indiscriminate medical relief afforded in various charities throughout the kingdom, approves of the general principles enunciated with the view of minimising the evil. Regarding the abuse of medical charities in Belfast, the opinion of the speakers was that it was not serious, and that the endeavours now made to prevent it were sufficient. It was also stated that the means of present abuse in the large general hospitals could not be used in the smaller and special hospitals to the full extent, so that while the general principles should be adhered to it might be advisable to vary the methods of carrying out these principles in accordance with the needs of different institutions.

SOUTH-EASTERN BRANCH.—There is a general agreement as to the recommendations of the Committee on Medical Charities. Most of the recommendations of the above Committee are practically carried out throughout the whole district over which the South-Eastern Branch extends. There is comparatively little abuse of the hospital system in our district. In many of the smaller provincial hospitals and dispensaries the funds would not be forthcoming to pay for an official to inquire into the pecuniary condition of each patient. This is hardly necessary, for in small towns the patients attending are better known than patients living in large districts; again, the information required of each person as asked for by the Committee, namely, that the name, age, residence, occupation, wages, &c., should be placed upon the hospital letter, is almost invariably done in this District of our Branch. Where a charity organisation society exists in any town it would be advisable, when in difficulty as regards the condition of the patient, to apply to its committee for information. It is the general opinion of our subcommittee that there is very much less abuse of the hospital system than existed ten or twenty years ago. This is doubtless due to the general agitation of the question by the medical profession themselves. The average wage limit for single men we

recommend should be 18s. to 20s. per week, and for married men 25s. There seems to be less abuse where the outpatient letters system is adopted than when the method of free admission is in vogue: as in the former, the difficulties of obtaining letters and the necessary knowledge requested thereon act as deterrents.

STIRLING, KINROSS, AND CLACKMANNAN BRANCH.—The recommendations were received with general approval, but it was not practicable at this time for the Branch to inquire into the abuse of medical charities in this district.

THAMES VALLEY BRANCH.—There are no large hospitals in our district. This Branch has taken no steps to investigate the abuse of medical charities.

WEST SOMERSET BRANCH.—It was mentioned by one of the medical staff of the Taunton and Somerset Hospital that the subject had been fully considered not long since by the Committee of that hospital, and such steps had been taken by them as were deemed best suited to deal with the abuse referred to, but they did not feel it right to incur the expense of a special "inquiry officer." The recommendations of the Committee will be sent to the Taunton and Somerset Hospital.

It is with great regret that we have to report the death of Dr. Withers Moore and of Dr. George Henty, both of whom devoted great attention to the work of this Committee, and whose places it will be difficult to fill. We are specially indebted to Dr. Henty for having personally visited, with Mr. Brown and Dr. Hugh Woods, and specially reported upon almost every hospital and medical charity in London.

THOMAS BRIDGWATER, M.D., *Chairman.*

REPORT OF COMMITTEE ON THE MENTAL AND PHYSICAL CONDITIONS OF CHILDREN.

YOUR Committee, first appointed in 1888, have worked continuously since that year, and now present a report completing the results of the investigations among 100,000 children seen individually 1888-94. Our first report was published in the *BRITISH MEDICAL JOURNAL* of July 27th, 1889, a committee of investigation being then appointed by the Charity Organisation Society, to which you nominated delegates; this Committee worked in conjunction with them, and presented a full report on 50,000 children (1883-91), which you forwarded to the Local Government Board, and which was subsequently published by the American Government. In 1891 the International Congress of Hygiene and Demography, which met in London, appointed a Committee to which you sent your representatives, and we have since worked in conjunction with that body.

Since 1892 the methods of actuarial investigation have been greatly improved, showing the advantages derived from a mixed Committee of members of the Association and actuaries, while your Committee have been able to conduct the observations and determine the directions the investigation should take, the assistance of actuaries and gentlemen acquainted with other branches of work has proved most valuable in compilation of the report. The children were seen and reported on by Dr. Francis Warner, in conjunction with Dr. Shuttleworth and Dr. Fletcher Beach. In our last report we presented a nomenclature or list of the defects observed in children, with definitions, showing also the numbers of boys and girls with each defect respectively as found among 50,000 children (boys, 28,287; girls, 23,713) seen, 1892-94. We are now able to present the same children in groups, defined by points seen or physical signs found to be present.

The principal indication of defectiveness of body and brain is found in defective development of the body and its parts as enumerated in the last report: the physiognomy and proportioning of the head, palate, the separate features, and conditions of growth. It is shown in Table III that such children present associated conditions in large proportion as indicating nerve defect or disturbance, especially the boys and delicacy or mental dulness, especially among girls.

The cases presenting nerve irregularities—abnormal nerve

signs—showed a high proportion of mental dulness (see Table III); these conditions are to a great extent removable by efficient training in school. In schools where such training is neglected the proportion of dull children rises. Low nutrition or delicacy of the body and its tissues is found in more than half the cases to be associated with developmental defect; these children bear the strain of life badly, yet need efficient training to keep their brains in good order.

Lastly, the children reported by the teachers as mentally dull or backward form a large group, especially among the boys: to the extent of 15 per cent. of the boys and 19 per cent. of the girls; they were also delicate children, very many also presenting indications of defect in body and in brain action.

That the physical signs or points for use in observation and description as employed throughout this inquiry are such as are worthy of record in clinical medicine and in investigation of the causes and pathology of mental dulness has been demonstrated by a large experience. The percentage of children with each sign who were reported by the teachers as dull or backward has been determined; it is now found that a large proportion of these children—amounting to about 30 per cent.—were over age for the educational standard in which they were placed, thus confirming the evidence that such children were dull or backward. Cases with defects were most frequent in the "classes for dull pupils" found in some schools. This fact shows the importance of reporting on the bodily and mental condition of children congregated on account of mental deficiency, as they are apt to present coexistent physical and brain defects.

Many of the problems dealt with in previous reports and papers written on this investigation have been confirmed by our later inquiry, and others are now given, supported by sufficient evidence to enable us to make recommendations, some of which appear to be of urgent social importance.

The marked differences in the make and in the constitutional power of boys and girls is strongly indicated. On reference to the numbers given in Table II, it is seen that the boys present more cases of defect, but reference to Table III shows that these defects are more associated with ill consequences in the case of girls. Cases delicate, thin and pale, without associated defects, are equally common among boys and girls. This suggests the desirability that in all returns of mortality and other vital statistics the numbers of males and females should be kept separate; also that "developmental diseases" equally with zymotic diseases should be included in the returns of medical officers of health.

Inspection of day schools has shown that there are cases of mentally feeble and afflicted children who may with benefit be kept in such schools under special training, and who cannot be justly excluded from the benefits of free national education on account of their feebleness; but the proper selection and classification of such cases should be entrusted to responsible medical men, and an individual report should be made annually upon all such cases. This class of children appears to form about 1 or 1.5 per cent. of the school population, a small proportion, but giving about 10,000 children for London alone. Our experience, which is supported by many correspondents, English and foreign, shows that both in this and in other countries there is a distinctly appreciable proportion of feeble-minded children and adults in all ranks of society who become a burden and source of danger to the public whom the State cannot afford to leave unduly. Such children were till recently but little recognised; efforts are now being made in many directions to aggregate them, suggesting the need of caution and of the scientific safeguards that prudence dictates for the careful selection, classification, and reporting that is desirable to ensure the proper management of these most difficult cases. Many such children are to be found in philanthropic homes, in certified industrial schools, and in punitive schools, where the discipline enforced is unsuited to the crippled, the deformed, and those mentally defective. Individual report on each case in such schools should be made annually. It is hoped that the earnest attention of many members of the profession may be directed to study these cases, and to the responsible work which some must

be called upon to discharge in connection with the care of defective children. Equally urgent is the need of a trained staff of teachers in whose training our profession should take a part.

Much pains have been bestowed on the arrangement of the best methods of reporting as to the mental and physical conditions of children who present some form of weakness calling for special care; a form of special report has been drawn up which may be found useful, especially in view of legislation now being promoted by the London School Board for the further care of weak children in day schools. The Committee have also devised methods of reporting on groups of children or groups of schools in such a manner as to enable their conditions to be compared together or with an established average, based upon a wide experience. In this way it is possible to compare the effects of the educational methods employed.

The 63 day schools reported on have been divided into groups as English, Scottish, Irish, and Jewish. The relative condition of these children is given in Table IV.

TABLE IV.—Showing the 60,000 Children seen 1892-94 distributed according to Nationalities, giving also Percentages of Children presenting certain Conditions.

D. Dull	42.8	44.4	55.0	62.0	12.5	19.0	—	—

Percentages indicate the proportion of cases named in first column with conditions as given in succeeding columns respectively.

FRANCIS WARNER, M.D., Hon. Sec.

REPORT OF ANÆSTHETICS COMMITTEE.

SINCE the reappointment of the Committee at the last annual meeting the work of analysing the records, deputed to a subcommittee, has been steadily continued. The subcommittee, assisted by a staff of clerks, resumed their meetings in October, 1894, and from that time till the present date have met on sixty-seven occasions, each meeting lasting at least two hours.

As the preparation of the final report has taken a much longer time than was at first anticipated, the Committee feel

that they should take this opportunity of presenting to the Council a short statement of the work which has been already accomplished, and an outline of the method upon which they hope to arrive at their conclusions.

The record books were returned to the Committee from the observers early in 1893, and these, supplemented by some special reports and by press cuttings during the year in which the observations were made, constituted the evidence which it was the business of the Committee to investigate.

By the time of the annual meeting of 1893 the cases in the observers' books had been arranged under the different anaesthetics employed, and counted, while abstracts of all cases of danger and death under chloroform, ether, and gas and ether had been printed, and a report upon these lines was in an advanced stage of preparation. Most of this work was done by the Honorary Secretary, with paid assistance, the Executive Committee of that year meeting frequently to confirm the classification of the cases of danger and death.

In October, 1893, it began to appear that unless every case in the record books, whether normal or complicated, was submitted to an exhaustive analysis, much valuable material would be lost. After much deliberation the Executive Committee determined to classify each recorded case, analysing it systematically in the most complete manner. After eighteen prolonged sittings the uncomplicated (or normal) cases contained in 42 of the record books had been thus dealt with as a trial of the method which had been adopted. It was then decided, on December 1st, 1893, that a subcommittee, consisting of Dr. Dudley Buxton, Mr. Eastes, Dr. Hewitt, and Mr. Rowell (as Honorary Secretary) should treat the whole of the cases in this manner. Fifty-three additional meetings took place for this purpose up to the time of the annual meeting of 1894.

During the past year the same system has been carried out, and on February 4th last the subcommittee—three constituting a quorum—had considered each recorded case, and had transferred all the analysed data of the uncomplicated cases to fourteen different analysis books which had been prepared for the purpose. Upwards of 23,000 uncomplicated cases had thus been submitted to an elaborate scheme of tabulation and cross tabulation. As a result of this any case can now be readily identified in the analysis books. Some idea of the diversity of the data which had to be transferred and tabulated in the analysis books may be gathered from the fact that records of the administration of no fewer than forty-two distinct anaesthetics, mixtures of anaesthetics, and successions of anaesthetics were sent in, the large proportion of which were administered in many different ways, and that all the particulars of each case—for example, age, condition of patient, nature of operation, phenomena during administration, after effects, etc.—had to be tabulated under the particular anaesthetic employed. During this analysis many doubtful points arose, upon which letters of inquiry were addressed to the observers, and the Committee wish to express their thanks to these gentlemen for the help afforded by their replies. Many points of interest were also found while going through the cases *seriatim*, each as it arose being noted for the final report.

Having completed this work, the Subcommittee was in a position to formulate the following definitions and scheme, to express their view of the character of the cases submitted to and classified by them:

DEFINITIONS.

Uncomplicated cases are those in which, so far as the effects of the anaesthetic are concerned, nothing unusual occurs.

Complicated cases are those presenting unusual symptoms or sequelae referable wholly or in part to the anaesthetic.

Cases with minor complications are those showing some noteworthy departure from the usual phenomena of the anaesthetic given, but not involving actual anxiety or danger.

Cases of anxiety are those presenting symptoms referable wholly or in part to the anaesthetic, and requiring the adoption of remedial measures, but not involving immediate danger.

Cases of danger are those in which symptoms caused wholly or in part by the anaesthetic threaten the patient's life.

Cases of death are those in which the death is wholly or in part due to the effects of the anaesthetic given.

SCHEME.

	I. Capable of Exact Classification.	II. Capable only of Approximate Classification.
A. Uncomplicated cases	---	---
B. Complicated cases	---	---
(a) Cases with minor complications ..	---	---
(b) Cases of anxiety	---	---
(c) Cases of danger ..	---	---
(d) Cases of death	---	---

C. Excluded Cases (that is, those which the Committee felt could not be included in Classes A or B).

Upon the foregoing basis the Subcommittee proceeded to reconsider every case which was not *prima facie* an "uncomplicated case capable of exact classification" (A.I.), with a view to the revision of its classification. This work, although long, was facilitated by reason of the analysis already completed. In the exact classification of a case the Committee would point out that there are often three or four unknown quantities to be measured, or at least to be approximately gauged. For example, the exact state of the patient's health, the effect of the surgical procedure, the amount of hæmorrhage, and the personal equation of the observer, may all conceivably effect a certain recorded case, and, when dealing with such, much time, care, and comparison with other cases have been found necessary.

At the present time (June, 1895) some 200 cases remain to be reconsidered, in order to complete the classification of every recorded case.

Upon the accomplishment of this, the Subcommittee propose to treat the whole of the complicated cases (B) by the same methods of analysis and tabulation as the uncomplicated cases have already undergone, for purposes of comparison, and the more easy deduction of conclusions. They propose, also, to abstract and print the whole of the cases in Class B, arranged in groups for the report. When this has been done the facts will be ready to hand for drawing up the final report.

The Committee desire to express their obligation to the following gentlemen who, as voluntary assistants, have given valuable help in the task of analysing the cases: Dr. Cecil Morgan, Mr. G. L. Eastes, and Messrs. Howard, Humphris, Vickers, and Byles. They also desire to record their thanks to the staff of clerks who have worked with much painstaking zeal.

The Committee trust that the time and labour devoted to this work by those who have been so long engaged upon it will sufficiently indicate their belief that results of considerable value will be attained.

The Committee therefore beg that the Council will reappoint them, in order that they may bring their work to a conclusion.

JONATHAN HUTCHINSON, *Chairman*.
CHRISTOPHER CHILDS, *Hon. Sec.*
GEORGE ROWELL, *Assistant Hon. Sec.*

REPORT OF THERAPEUTIC COMMITTEE.

During the past year the Therapeutic Committee have held numerous meetings to consider the approaching revision of the *British Pharmacopœia*, and they have considered carefully various alterations, omissions, and additions, and have embodied their views in a Memorandum which was printed in the *BRITISH MEDICAL JOURNAL* of June 8th.

With regard to possible omissions, it was thought desirable to circulate amongst members of the Association in the United Kingdom a list of drugs and preparations, with a request that each member should indicate whether he used these drugs often, rarely, or never. Of this list, 12,000 copies

have been issued, and, at the time of tabulation, answers had been received from about one half of this number. The data thus collected have been placed at the service of the General Medical Council, and a cordial letter, recognising the material assistance thereby furnished, has been received from the President.

The information elicited in this inquiry is of considerable interest, and must materially influence the retention or omission of drugs from the *Pharmacopœia*; thus its great value to the medical profession can scarcely yet be estimated.

The Committee hope, during the ensuing year, to pursue investigation of numerous questions which have arisen in connection with the *British Pharmacopœia*, both concerning the introduction of newer remedies and the improvement of older Galenic formulae.

SENATOR THIRARD, Hon. Sec.

REPORT OF COMMITTEE FOR THE EFFICIENT CONTROL OF RAILWAY SERVANTS' AND MARINERS' EYESIGHT.

THE most important action taken by the Committee during the past year was the organisation of a deputation of ophthalmic surgeons, which waited upon the President of the Board of Trade (the Right Hon. James Bryce, M.P.), at Whitehall, on February 1st, 1895.

The composition of the deputation, the names of the speakers, and an abstract of the speeches, have already been published (see *BRITISH MEDICAL JOURNAL*, February 9th, p. 315, and May 18th, p. 1112).

The Committee takes this opportunity of thanking all those gentlemen who supported it upon that occasion. A more important representation of ophthalmic opinion could scarcely have been secured in this country, and the "weight and influence" of the deputation was fully acknowledged by Mr. Bryce.

The Committee has reason to believe that, if the results of its action are not immediately apparent, it has at least impressed upon the permanent officials of the Board of Trade the importance of including defects of vision among the possible causes of disaster by land and sea, and has excited a public interest in the subject which will not soon pass away.

THE PRESENT POSITION OF THE QUESTION ON THE RAILWAYS OF THE UNITED KINGDOM.

The Board of Trade has at present no power to enforce any uniform system of eyesight testing on our railways, and, as indicated by Mr. Bryce in his reply to the deputation, the Government officials are unwilling to ask for further power until some grave accident shall be proved to have been caused by defective vision. Considering the very unsatisfactory methods of examination still employed on some railways, this inaction is not commendable. But apart from the possibilities of jeopardy to the public which this policy entails, there can be no question that the adoption and enforcement by properly qualified examiners of uniform standards of vision for railway servants would be of the greatest advantage to the men, and would considerably lighten the responsibilities of the railway managers in promoting desirable reforms.

Under the present system, by which each company is left to adopt its own standards, there is no security for the men that these may not be altered at any time.

The hardship of such a change was well illustrated during the past year, when the North British Railway officials, having determined to increase the stringency of their examinations, found themselves obliged to dismiss from their employment, or transfer to positions of less responsibility at reduced wages, more than 100 drivers, firemen, and guards, many of whom had seen several years' service. Nearly all of these were rejected for defective sight (*not colour blindness*), and yet this company even now requires no higher standard than the army dot test, or, in other words, men with *any* method of normal vision can still be admitted.

This test is now used on many railways. Its insufficiency is already recognised by a few of the more progressive railway managers, and, as the number of these increases, the weeding-

out process will again press hardly on men who should never have been admitted to railway responsibilities, and who, if they had been properly examined at the outset of their careers, and warned in time, might have found more permanent occupation in industries better suited to their visual capacity.

There is undoubted evidence, however, on all sides that the railway companies are now attaching more importance to visual examinations, and it may fairly be claimed that, during the past year, some progress has been made towards the more effective control of railway servants' eyesight.

THE CONTROL OF MARINERS' EYESIGHT.

In September, 1894, the new regulations for the examination of the eyesight of masters and mates in the mercantile marine came into force. The adoption of Holmgren's test for colours and the introduction of a test for distant vision mark an important advance in the official modes of testing, but grave defects still exist in the present methods of control. For instance, boys are apprenticed to the sea without compulsory examination of their acuteness of vision or colour sense, and cannot legally escape from their indentures should their vision be found later to be defective. Similarly men are allowed to serve at the wheel or on the look-out without any inquiry as to their visual fitness. No visual examination is enforced until promotion to officer's rank is sought, and, needless to say, rejection is then harder to bear, and a false start in life is less easily remedied. The employment of lay examiners and the omission of refractive measurements increases the liability to error in judging of the visual capacity of candidates. These deficiencies and some suggestions for their removal were duly laid before Mr. Bryce, and are fully stated in the *BRITISH MEDICAL JOURNAL* of May 18th, pp. 1112 and 1113.

The Committee desires to express its special obligations to Mr. Bickerton, of Liverpool, for his admirable exertions in this connection.

It is satisfactory to know that the reforms which were urged upon Mr. Bryce were heartily endorsed by several societies of shipping and navigating officers, and that only a regard for Mr. Bryce's expressed wish that the deputation should be limited to medical men prevented a very definite expression of opinion being submitted to him by representatives of the above societies in favour of the Committee's recommendations. Under these circumstances the Committee is encouraged to persevere in its labours, and requests a continuance of its appointment.

N. C. MACNAMARA, *Chairman*.
GEORGE MACKAY, *Hon. Sec.*

DONARIA OF MEDICAL INTEREST.

By DR. LUIGI SAMBON,
Rome.

(Concluded from page 150.)

AMONGST some terra-cottas sent to me from Capua, I found two perfect models of the placenta; they probably came from the Temple of Maternity which was discovered there.

In a heap of broken terra-cottas and marble fragments piled outside the new museum of the "Orto Botanico" in Rome, I found a most interesting votive terra-cotta. It represents an elbow, on the extensor aspect of which are numerous thick circular patches generally of the size of a three-penny bit. This elbow is not a fragment of a statue, but a donarium of the arm from which the hand alone has been broken off. The patient having offered the representation of an arm, it is natural to believe that that limb only was affected by the disease. The patches are limited to the point of the elbow and to the immediate neighbourhood. If diagnosis of skin diseases is often difficult on the living subject, it must seem almost impossible on a rough terra-cotta made for no scientific purpose by a simple potter many centuries ago, but curiously enough the diagnosis in our case is relatively easy, the donarium offering apparent signs of psoriasis. The only doubt might arise from psoriasisform syphilides and the little difference in size of the various nodules would be in favour of a manifestation of this disease, which seems to have been

known to the Romans under the name of *morbus campanus*, but syphilides appear mostly on the flexor surface of the limbs which in our terra-cotta is entirely free from the disease.

Fig. 11.—Psoriasis of elbow (Rome).

Psoriasis and other similar diseases were known to the ancients by the name of *lepra*, which meant roughness, and must not be confounded with leprosy.

Together with these images of anatomical parts there have

Fig. 12.—A kidney (Capua).

nearly always been found numerous statuettes greatly varied in subject and treatment, many presenting points of medical interest on close observation. Similar statuettes have also been found apart from votive offerings, often in tombs and not only in Italy and Sicily, but also in Greece, France, Spain, Asia Minor and Africa. Those of Tanagra in Greece have attracted most attention on account of their great beauty.

Much difficulty has hitherto been experienced by archaeologists in understanding the subject of many of these statuettes and their use. Some have considered them all as connected with funeral rites, although few offer subjects that can be related to the grave. Many of those found in tombs had been placed there by the relatives simply as things to which the deceased had been most attached during life. Other writers believe them to have been domestic ornaments or household gods which were kept apart in small shrines such as the *sacrum* represented at Pompeii. Archaeologists have frequently erred in believing all the figures to be images of gods and goddesses, and wishing to find a mythological explanation for each group. A certain

number are undoubtedly representations of deities, but I believe the majority to be donaria representing patients or devotees in the act of adoration or bringing gifts to the gods. The gift most acceptable to each god being generally also an attribute or symbol of the same has often led to the error of mistaking the representation of the worshipper offering donaria for the image of the deity. Some were undoubtedly toys. I have no doubt that the explanation given here of many terra-cotta statuettes instead of a far-fetched mythological interpretation will make their classification far more easy. Many statuettes which have been classed by archaeologists among grotesque figures are representations of patients bearing signs of deformity from disease most admirably depicted. Obesity, dropsy, rickets and other diseases are clearly represented. Some statuettes represent patients unclothing the part of the body diseased so as to attract the attention of the deity to their infirmity. They remind us of the numerous beggars exposing their sores and deformities to the passers-by who may be seen even now in many towns of Italy. Such figures represented as uncovering a part of their body have generally been mistaken for obscene representations.

A large and most interesting series of terra-cotta figures is connected with childbirth and lactation. Many are the images of women in labour. Some are in the kneeling position, a favourite one in the first stage of labour, still common in many parts of Italy. This position was naturally and instinctively changed to the knee-elbow or to the genu-pectoral position at the time of expulsion. A marble votive bas-relief of my collection found near Rome shows a woman just delivered in the knee-elbow position. The kneeling figures are also represented with both hands on the abdomen performing a kind of uterine expression. In this same position

Fig. 13.—Parturient woman in the kneeling position, perhaps a Nixi. (Oppenheimer Collection.)

were represented the Nixi, Roman deities to which petitions were made for a rapid and safe delivery.

Other parturient women are represented in the sitting position, sometimes on a kind of obstetrical chair. In the

Louvre Museum in Paris is a terra-cotta group of a parturient woman in the sitting position leaning against another woman who holds her from behind, while the oestriatrix or midwife in front of her has received the new born child. A similar group in marble found at Cyprus in 1871 by General Conzatti is now in the New York Museum.

A frequent subject in old Roman sculpture is the birth of Bacchus by Caesarian section from the corpse of Semele. This operation was often performed *post mortem matris*. It is said that Julius Caesar and Augustus Alvanus were born thus.

Very numerous are the figures referring to disorders of lactation or diseases of the breasts, from the very old rigid images pressing both mammae with their hands to the graceful, seated figures of later art sweetly smiling on their suckling infant. Some are represented supporting with their hands an inflamed breast, others holding fissured and ulcerated nipples. A few hold a vessel beneath one breast evidently affected by galactorrhoea. A terra-cotta in my collection represents a young woman with an enormous left breast due to hypertrophy or to some new growth. Some women hold a child on one arm, while with the other hand they point to the breast glands imploring lactation.

There are groups of figures representing a husband and wife sitting side by side, the woman generally presenting

Fig. 14—Husband and wife offering thanks for offspring. Group found in the Tiber by the Insula Sacra.

evident signs of pregnancy. Very often a child is seated between them or in the mother's lap. They represent grateful people offering a thanksgiving for offspring after a long period of sterility, although they have again and again been described as Demeter with the infant Bacchus. Women raising the right hand opened in the act of adoration and holding in the other hand a pomegranate with bursting rind are not images of Venus but barren women imploring pregnancy.

Children with arms and legs tightly bound in swaddling clothes, as is still the custom in Italy, are of common occurrence. They were frequent offerings of anxious mothers.

Children represented dragging themselves along in a crouched position with contracted and atrophied legs, are certainly cases of infantile paralysis or sometimes pronounced lordosis, cases of rickets with powerless and wasted lower limbs.

Figures of hermaphrodites have been found amongst the votive terra-cottas; sometimes a bearded figure in female clothes and adornments with rounded forms and swollen breasts; at other times figures with female features and male genitals. I have in my collection a terra-cotta of a tall graceful woman disarranging her clothes to show a clitoris enormously hypertrophied.

A large number of figures of both sexes, generally standing and entirely wrapt up in clothing, may, possibly, represent

fever-stricken patients. Malaria, which prevailed in many places with far greater virulence in summer and autumn, was a dreaded disease as is proved by the many altars erected to Febris and Mefitis. Febris had three temples in Rome, and only a few years ago the goddess of fever was still worshipped under the name of Madonna delle Febri at the foot of the Vatican hill in a place called the Valley of Hell.

Numerous figures of animals are found amongst the other votive terra-cottas, mostly domestic animals. Horses and oxen are very common, but pigs are by far the most numerous. Pigs are often ornamented all over by geometrical designs or studded with bits of coloured glass. Some are represented with children on their backs. These figures of animals may in some cases have been symbolical offerings of animals sacrificed but they were generally brought to the shrine for disease, especially at the time of cattle plague. The single heads, feet, or internal organs of animals which are often found confirm this view. The children carried on the back of pigs may be connected with the worship of the goddess Carna, a very ancient goddess who strengthened the heart and entrails. The pig was sacred to her, and on the first of June it was sacrificed, when those who ate of the hind believed themselves to be preserved from all intestinal disease. Children suffering from wasting diseases were taken to the temple of Carna and fed upon raw pork as directed by the priests of the goddess. A bronze statuette found in Naples represents a woman carrying an infant on her left arm and holding with her right hand a sucking pig by its hind legs. Brutus the first consul erected a temple to this goddess on the Velian hill.

All these terra-cottas were painted in various colours, mostly red and blue, as exemplified by the remnants of pigmentation still visible on some of them. The eyes and hair of the statuettes were generally black; yellow was not a common colour and green and gold were rarely used. Before applying colours the terra-cottas were dipped in a bath of lime and many which have lost the colouring have retained this white coating. Some few were covered with a glaze which produces the appearance of an enamelled surface. The colour having disappeared from these terra-cottas has no doubt deprived us of much additional information.

Except the earliest examples, which are rudely modelled with the hand, these statuettes were made from clay moulds, many specimens of which still exist. The mould was only used for the front of the figure, the back of it being, as a rule, merely a plain piece of clay shaped by the hand. If any design was desired at the back also, it was invariably executed by the hand. Sometimes the head, the arms, and other accessories were added afterwards; thus two casts from the same mould differed considerably.

The terra-cottas found in the same votive deposit often belong to very different periods and localities. The most archaic types are sometimes found with those of the latest and purest art. To a certain extent they can be distinguished by the different quality of clay, the different firing, and by peculiarities of treatment and colouring. But great caution is necessary in determining their age or locality on account of the long continued and faithful copying of the old hieratic idols, the persistency in use of old moulds, the exchange of moulds, the migration of workmen, and the local reproduction of foreign images, often by casts.

These terra-cottas pressed out of the clay in vast numbers were sold together with other donaria in the neighbourhood of the temples, as in our days the scapulars and images of saints can be purchased at the doors of churches.

In some places, similar images have been found made of tufa. Marble donaria are not so common; two fine specimens are in the Vatican museum, one of these represents the chest of a child dissected in the middle line; the organs thus exhibited are not free from mistakes. The other represents the thoracic skeleton of an adult; it has thirteen ribs on each side. Both these marbles were found in the Tiber by the Insula Sacra (Island of S. Bartolomeo) where a temple had been erected to Asclepias. This temple had the form of a ship in memory of the famous embassy which had been sent to Epidaurus to fetch the god of medicine, this being ordered by the Sybilline oracle during a great plague which devastated Rome in the year a. c. 291.

Bronze donaria are more numerous; they represent, like

the terra-cotta, figures of gods, patients offering gifts, domestic animals, or various parts of the body. The figures, which generally vary in size from two or three to twenty inches, were generally fixed by means of lead to small bases of tufa, marble or *travertine*, some of which bear votive inscriptions. These pedestals were square or conical in shape and always scooped out at the top. Some of the images had lead or bronze pedestals or no base whatever, and were made to be thrown into the water. Amongst the bronze donaria of my collection is a model of the scalp with neatly plaited hair, a votive offering, probably to Minerva Medica, for recovery from loss of hair. At *Faltermora* many interesting pathological bronzes were found. Bronze figures of leeches are of common occurrence.

In the temples were also placed wove tablets of wood or terra cotta on which were paintings of miraculous healings and portraits of divinities or donors; they were also hung about the walls with the other offerings or on the sacred trees. All things thus suspended were called *osella*.

A curious sight must have been the old temples crowded with donaria of all kinds, which filled up each corner, covered the walls, hung from the ceilings, clustered round the shapeless *roama* or the beautiful statues of gods, like swarms of bees. The deep red terracotta limbs and blue coated statuettes contrasted with the white bas-reliefs of marble, while bright donaria of bronze and gilded offerings shone among the gorgeously coloured tablets. All these offerings told one tale of human suffering and divine charity. Together with the inscriptions which covered pillars and walls they recorded dreadful diseases and wonderful cures. Every day new donaria were collected, new miracles registered. The temples became interesting museums, great schools of medicine and many eminent men, amongst whom was Hippocrates, learnt in them the principles of medical science. Tablets were chiselled on walls and pillars as on the leaves of a great book, profusely illustrated by the never ending rich donaria. At an early date a regular profession of medicine sprang up and attained considerable importance. All specialities were soon represented as largely as in our modern days, and wonderful operations were successfully performed, but the old temples, strongly founded on faith, were always crowded.

Sir William Hamilton published in 1780 a description of the feast of Sts. Cosmas and Damian in Isernia (near Naples), which continued unchanged to only a few years ago. I give here an abstract of some parts which bear closely on our study:

19 In Isernia, at the annual fair which is held on September 27th, exvoti of wax representing different parts of the body, but especially the male parts of generation, are publicly offered for sale. The devout distributors of these votive offerings carry a basket full of them in one hand, and hold a plate in the other to receive the money, crying aloud 'SS. Cosmo e Damiano.' If you ask the price of one, the answer is 'The more you give the more's the merit.' In the vestibule are two tables, at each of which one of the canons of the church presides, crying out this 'Here masses and intonies are received,' and the other 'Here the votive offerings are received.' The price of a mass is 15 Neapolitan grani (5 pence), and of a litany 5 grani (about 2 pence). On each table is a large basin for the reception of the different offerings. The votive offerings are chiefly presented by the female sex.

"At the great altar in the church, another of its canons attends to give the holy unction with the oil of S. Cosmo, which is prepared by the same receipt as that of the Roman ritual with the addition only of the prayer of the holy martyrs SS. Cosmo and Damiana. Those who have an infirmity in any of their members present themselves at the great altar and uncover the member affected, the priest anoints it, saying, 'Per intercessionem beati Cosmi, liberet te ab omni malo.'"

In nearly all the churches of Italy and often at the small shrines in the streets are numerous votive offerings in wax, silver and wood many of which have only been recently consecrated, but the modern donations are of no interest compared with those of the ancients.

MIDWIVES REGISTRATION

THE text of this Bill in the House of Lords has been modified on several important respects owing to the amendments adopted on report. We therefore print the Bill as it stood at the close of the last Parliament. The text of the Bill as introduced by Lord Balfour of Burleigh was published in the *BARTON MEDICAL JOURNAL* of May 11th, pp. 1055, 1056.

We subjoin also the text of the "Middlesex Surron Act" drafted by a Subcommittee of the Parliamentary Bills Committee, consisting of Dr. R. W. Batten (Gloucestershire Branch), Dr. Spottiswoode Cameron (Yorkshire Branch), Mr. E. H. Galton (South Eastern Branch), Professor Victor Horsley (Metropolitan Counties Branch), Mr. Evan Jones (North Wales and Monmouthshire Branch), and Mr. S. Woodcock (Lancashire and Cheshire Branch).

MIDWIVES REGISTRATION BILL

HOUSE OF LORDS.
ANNEXED ON REPORT.

He is enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

- Short Title.**—This Act may for all purposes be cited as the Midwives Act, 1902.
- Definitions.**—In this Act "Midwives Register" means a register of midwives kept in pursuance of this Act; "Midwives Board" means the Board constituted under this Act for the purpose of carrying out the provisions of the Act.
- Register of Midwives.**—A midwives register shall be established under this Act, and subject to the provisions of this Act any woman shall be entitled to be registered therein as a midwife who passes the qualifying examination held for the purpose under this Act.
- Registration.**—(1) From and after the expiration of eighteen months from the date of the establishment of the midwives register a woman shall not take or use the name or title of midwife (or any combination with any other word or words), or any name, initials, or description implying that she is registered under this Act, unless she is qualified to act as a midwife, unless she is registered under this Act.
- (2) If any person acts in contravention of this section, it shall be liable on summary conviction to a fine not exceeding five pounds.
- (3) Nothing in this section shall apply to legally qualified medical practitioners.
- Priileges of Registration.**—From and after eighteen months from the date of the midwives register, no woman shall be entitled to recover any fee or charge in any court for attendance or service rendered as a midwife unless such woman be registered under this Act. A woman shall not by reason of being registered as a midwife under this Act have any right or title to be registered under the Medical Act, 1857, or the Acts amending the same, or to assume any name, title, or designation implying that she is by law recognised as a licentiate or practitioner in medicine or surgery, or that she is qualified to grant any medical certificate or any certificate of the cause of death.
- Provision for Existing Midwives.**—Any woman who at the passing of this Act is in bona fide practice as a midwife, or has obtained a certificate in midwifery from some hospital or workhouse infirmary, or from the Royal College of Physicians of Ireland, or from the Obstetrical Society of London, or such other certificate as may be approved by the General Medical Council, and claims to be registered before the expiration of two years from the passing of this Act, and produces the certificate so required to her to be so registered, shall be entered on the midwives register at such reduced fee as the Midwives Board shall prescribe.
- The Midwives Board.**—(1) Within six months from the passing of this Act a Midwives Board shall be formed, which shall consist of twelve named medical practitioners, three to be appointed by the Royal College of Physicians of London, three by the Royal College of Surgeons of England, three by the Apothecaries, and three by the Incorporated Midwives Institute, and of three persons in addition to be appointed by the Lord President of the Council, of whom one at least shall be a woman. One of each of the sets of three members so appointed shall retire in every year, and his place shall be filled by a fresh appointment made in the same manner as the original appointments were made.
- (2) A resolution passed by the majority of the whole of the members of the Board shall be valid for the purposes of this Act, and of any rules made thereunder, the Midwives Board shall, in addition to any other duties under this Act,—
- (a) Establish and keep the midwives register under this Act, and provide for holding qualifying examinations, or causing the examinations to be held if necessary, and appoint examiners; (b) Issue to the persons where and how often when examination shall be held; (c) Make regulations for governing their own conduct; (d) And generally do any such duty as may be required to be done and performed by them by the provisions of this Act, or the Privy Council, or the General Medical Council, and shall also have power to appoint one of the first Midwives Board in conformity with the provisions of the Privy Council, and call the first meeting thereof, and the second meeting thereof, and have the same powers as are conferred upon the Local Medical Officers of Health by the Public Health Act, 1872, and the amendments thereof, and the powers conferred upon the Local Medical Officers of Health by the Public Health Act, 1891, and the amendments thereof, and the powers conferred upon the Local Medical Officers of Health by the Public Health Act, 1900, and the amendments thereof, and the powers conferred upon the Local Medical Officers of Health by the Public Health Act, 1902, and the amendments thereof.

wives register, and give notice thereof in the London Gazette, and the day so fixed is in this Act referred to as the date of the establishment of the midwives register.

3. Rules for the Examination of Midwives.—(1) For the purpose of the examination of women desiring to be registered as midwives the Midwives Board shall, as soon as may be after the passing of this Act, frame, subject to the approval of the General Medical Council, rules regulating the method and subjects of the qualifying examination, and the general standard to be attained by persons passing the examinations with a view to secure the possession of adequate knowledge and skill in midwifery by all persons who pass such examinations. (2) The Midwives Board shall make rules as to the conduct and superintendence of examinations, as to the number of ordinary examinations to be held, as to the places of examinations, as to the regulation of registered midwives, and as to the steps to be taken to keep the register correct. The rules shall provide for the examinations being held, so far as possible, at such places as will enable persons to be examined within a reasonable distance from the place where they reside. (3) All rules made under this section shall be submitted to the Privy Council for confirmation, and certified copies of the rules when so confirmed shall be forthwith forwarded in duplicate by the Privy Council to Her Majesty's Stationery Office for official publication. In the event of the General Medical Council failing to perform the duties entrusted to it under this Act, the Privy Council shall invite some other suitable body to undertake these duties, or shall itself forthwith proceed to do so.

4. Fees and Expenses.—There shall be payable by every woman presenting herself for examination a fee of two guineas, should a candidate fail to pass, then for her second or any subsequent examination the fee shall be half a guinea. In respect of registration, the fee shall be five shillings. All fees paid by midwives or by candidates for examination shall be paid to the Midwives Board. Each Board shall devote such fees finally to the payments connected with the examination and registration, so far as to the general expenses of the Board.

5. Supervision of Practising as to Register.—(1) The midwives register kept by the Midwives Board shall be open to inspection at all reasonable times on payment of such fee not exceeding one shilling as may be fixed by the Midwives Board. (2) The midwives register shall be deemed to be in proper custody when in the custody of such officer as the Midwives Board may appoint to keep the same, and shall be deemed to be of such a public nature as to be admissible in evidence on its mere production from that custody. (3) The Midwives Board shall cause copies of the midwives register to be printed, and shall at least once a year cause a new and correct edition of such copies to be published and sold, and such copies shall be admissible in evidence. (4) The Midwives Board shall, on the publication of each new edition of the copies of the midwives register, supply one copy to the council of every county in England and Wales free of charge.

6. Power of County Councils to Pay Expenses of Re-examinations.—(1) The council of an administrative county may require the Board to hold any examination in their county in addition to those usually held on payment of the expense of such additional examinations, and may pay any such expenses out of the county fund. (2) This section shall apply to a county borough with the substitution of borough fund or rate for county fund.

7. Removal of Name from Register.—(1) Where a registered midwife is convicted of any felony or misdemeanour, or an inquiry held by the Midwives Board either on a complaint under this Act or otherwise is found to have been guilty of professional misconduct, the Midwives Board may remove her name from the midwives register. (2) Where the name of a registered midwife has been removed from the midwives register under this section, the name shall not be again entered in the register except by the direction of the Midwives Board, or the Privy Council, or a court of competent jurisdiction. (3) If the Midwives Board think fit, they may restore any name removed under this section to the register either without fee or on payment of such fee, not exceeding two shillings and sixpence, as the Midwives Board fix. (4) If in any case the Midwives Board decide to remove the name of a midwife from the register under this section, or not to restore to the register the name of any midwife, the Board shall on application by the midwife state in writing their reasons for the decision, and the midwife may appeal to the Privy Council, and the Privy Council, after consultation with the Board, may either dismiss the appeal or order the Board either not to remove the name or to restore the name, as the case may require. (5) For the purposes of this section, professional misconduct shall, in addition to any other form of misconduct, include any omission to send for a medical practitioner where the case is not one of natural labour.

8. Exercise of Powers by Privy Council.—(1) The powers by this Act vested in the Privy Council may be exercised by any two or more of the Privy Council. (2) Any order of the Privy Council may be made conditionally or unconditionally, and may contain such terms and directions as the Privy Council think just.

9. Complaints of Misconduct on Part of Registered Midwives.—(1) If any person has reason to complain of any professional misconduct on the part of a registered midwife, that person may complain either directly to the Midwives Board or to the medical officer of health of the district, or to the council of the county, or the district council of the district in which the misconduct is alleged to have occurred or the midwife usually practices, and it shall be the duty of the medical officer of health to report any complaint made to him to the council by whom he is appointed. (2) Any council to whom any such complaint is made or reported shall forward the complaint to the Midwives Board, and that Board shall inquire into it and give the council by whom the complaint was made information as to the result of their inquiry.

10. Notice of Death of Midwives.—Every registrar of deaths in England and Wales shall on receiving notice of the death of any registered midwife forthwith transmit by post to the Midwives Board a certificate under his hand of such death with the particulars of the time and place of death on the receipt of such certificate the Midwives Board shall cause the name of the midwife to be erased from the midwives register, and shall transmit to the said registrar of death such sum as the Treasury may fix not exceeding two shillings and sevenpence for the cost of the certificate and transmission.

11. Penalty for Obstructing Registration by False Representation.—Any woman who wilfully procures or attempts to procure herself to be placed on the register of midwives by making or procuring, or causing to be made or procured, any false or fraudulent declaration, certificate or representation, either in writing or otherwise, and any person assisting her therein shall be deemed guilty of a misdemeanour, and shall on conviction thereof be liable to a fine not exceeding ten pounds, or to be imprisoned, with or without hard labour, for any term not exceeding three months.

12. Penalty for Willful Publication of Register.—If any person appointed to keep the register of midwives, wilfully makes or causes to be made any falsification in any matter relating to the register of midwives he shall be deemed guilty of a misdemeanour and shall be liable to a fine not exceeding twenty pounds, or to be imprisoned with or without hard labour for any term not exceeding six months.

13. Prosecution of Offences.—Any offences under this Act punishable on summary conviction may be prosecuted, and any fine under this Act recoverable on summary conviction may be recovered, in manner provided by the Summary Jurisdiction Acts.

14. Appeal.—Where any woman deems herself aggrieved by any order, conviction, judgment, or determination of, or by any matter or thing done under this Act by any court of summary jurisdiction, such woman may appeal therefrom to the court of quarter sessions.

15. Extent of Act.—This Act shall not extend to Scotland or Ireland.

A BILL TO PROMOTE THE BETTER TRAINING OF WOMEN AS MIDWIFERY NURSES, AND FOR THEIR REGISTRATION AS SUCH.

Enacted by the Queen's Most Excellent Majesty by and with the advice and consent of the Lords Spiritual and Temporal and Commons in this present Parliament assembled and by the authority of the same as follows:

1. Short Title.—This Act may for all purposes be cited as the Midwifery Nurses Act, 1895.

2. Definitions.—In this Act the term "midwifery nurse" means a woman who undertakes to attend cases of natural labour.

"Midwifery Nurses Register" means a register of midwifery nurses kept in pursuance of this Act.

"Midwifery Nurses Board" means the Board constituted under this Act for the purpose of carrying out the provisions of the Act under the direction of the General Medical Council.

3. Registration.—(1) From and after the first day of January one thousand eight hundred and ninety-six no woman shall be entitled to take or use the name or title of midwifery nurse or midwife (either alone or in combination with any other word or words), or any name, title, addition, or description implying that she is registered under this Act or is in fact possessed of the skill necessary to act as a midwifery nurse or midwife, unless she be registered under this Act.

(2) Any person who after the first day of January one thousand eight hundred and ninety-six not being registered under this Act shall take or use the name of midwifery nurse or midwife, or any other name, title, addition, or description as aforesaid, shall be liable on summary conviction to a fine not exceeding five pounds, provided that nothing in this section shall apply to registered medical practitioners.

(3) No woman shall be placed on the midwifery nurses register until she shall have complied with the rules and regulations for admission to registration to be laid down in pursuance of the terms of this Act by the Midwifery Nurses Board acting under the direction of the General Medical Council.

4. Privileges of Registration.—A woman registered under this Act shall be entitled to act as midwifery nurse in England and Wales. From and after the first day of January one thousand eight hundred and ninety-six no woman shall be entitled to recover any fee or charge in any court for attendance or service rendered as a midwifery nurse unless such woman be registered under this Act, and the certificate of registration under this Act shall be a certificate entitling a woman to act as a midwifery nurse in cases of natural labour only in accordance with the prescribed regulations made in pursuance of the terms of this Act. A certificate under this Act shall not confer upon any woman any right or title to be registered under the Medical Act, 1858, or the Acts amending the same in respect of such certificate, or to assume any name, title, or designation implying that she is by law recognised as a licentiate or practitioner in medicine, or surgery, or midwifery except in cases of natural labour, or that she is qualified to grant a certificate of death, or of stillbirth, or any medical certificate.

5. Provision for Existing Midwives.—Any woman who at the passing of this Act has been in bond *de facto* practice as a midwife for a period of not less than one year, or has obtained such certificate in midwifery as may be approved by the General Medical Council, and claims to be registered before the expiration of two years from the passing of this Act and produces to the satisfaction of the General Medical Council both evidence of her title to be so registered, and evidence of good character, shall be entered on the midwifery nurses register at such reduced fee as the Midwifery Nurses Board shall prescribe.

6. Constitution and Duties of Midwifery Nurses Board.—Within six months of the passing of the Act a Midwifery Nurses Board shall be formed, which shall consist of twelve registered medical practitioners to be appointed by the General Medical Council. One-fourth of the members of the Board shall annually retire, but shall be eligible for re-election during a period not exceeding five years. The duties of the Midwifery Nurses Board shall be as follows:

- (a) To lay down rules for education and training for qualification of midwifery nurses.
- (b) To make rules for conducting and superintending the examinations for qualification of midwifery nurses.
- (c) To conduct the examinations and appoint the examiners.
- (d) To decide upon the places where and the times when examinations shall be held.
- (e) To frame for approval by the General Medical Council rules for regulating the practice of midwifery nurses.

(2) To investigate and to report upon all cases of complaint made against any midwifery nurse to the General Medical Council.

(3) And generally to do any such duty as may be necessary for the due and proper carrying out of the provisions of this Act.

7. *Terms and Examinations of Candidates.*—For the purpose of the examination of women desiring to act as midwifery nurses the Midwifery Nurses Board shall, as soon as may be after the passing of this Act, frame, subject to the approval of the General Medical Council, rules regulating the conditions of admission to examination, the course of study to be pursued previous to examination, the method, the period, and the subjects of such examination, and the general standard to be attained by women passing the examination.

The General Medical Council shall submit the rules approved by them to the Privy Council for confirmation, and the rules when so confirmed shall be forthwith officially published under the superintendence of Her Majesty's Stationery Office.

8. *Fees and Expenses.*—There shall be payable by every woman presenting herself for examination such fee as the Midwifery Nurses Board may, with the approval of the General Medical Council, from time to time determine. Should a candidate fail to pass the fee paid by her for any subsequent examination shall not exceed half the amount of the first fee. All the expenses of the Board shall be defrayed by the General Medical Council, and all moneys paid in respect of fees or otherwise shall be paid to the Treasurer of the General Medical Council.

9. *Register of Midwifery Nurses.*—The General Medical Council shall provide by their regulations for the keeping, and the publication from time to time, of a register of midwifery nurses.

10. *Publication of Register.*—The General Medical Council shall cause a new edition of the register kept by them under this Act to be printed and published on the first day of January in each year, and a copy of such register for the time being shall be evidence in all courts that the women therein specified are registered according to the provisions of this Act, and the absence of the name of any woman from such copy shall be evidence, until the contrary be made to appear, that such woman is not registered according to the provisions of this Act. Provided always, that in the case of any woman whose name does not appear in such copy, a certified copy under the hand of the registrar of the entry of the name of such woman on the register shall be evidence that such woman is registered under the provisions of this Act.

11. *Local Registration.*—Each medical officer of health throughout England and Wales shall be supplied with a copy of the register from year to year, and he shall keep this register accessible at all reasonable times for public inspection. No midwifery nurse shall commence practice in any district until she has first produced her certificate of registration to the medical officer of health for the district in which she purposes to practice.

12. *Notice of Death of Midwifery Nurses.*—Every local registrar of deaths shall at once transmit the death of any midwifery nurse in his district to the Registrar of the General Medical Council, with particulars of time and place of death, and may charge the cost of such certificate and transmission as an expense of his office, and on receipt of such certificate the Medical Registrar shall erase the name of such deceased midwifery nurse from the register.

13. *Removal from the Register.*—If any midwifery nurse shall be convicted in England or Ireland of any felony or misdemeanor, or in Scotland of any crime or offence, or shall after due inquiry be judged by the General Medical Council to have been guilty of infamous conduct in any professional respect, the General Medical Council may, if they see fit, direct the Registrar to erase the name of such midwifery nurse from the register.

14. *Restoration to the Register.*—The General Medical Council may after due inquiry restore to the register the name of any midwifery nurse removed therefrom.
